Krevans noted that all public and private health science schools in California spend a total of about $900,000 a year on the dogs and cats used in medical research. He estimated this figure could rise as high as $20 million for the University of California system alone if only specially bred dogs were used.

In addition, Joseph S. Spinelli, a veterinarian and director of UCSF's animal facility, said that specially bred animals are sometimes inadequate because they do not contain the genetic diversity important in some types of research. Spinelli also emphasized that research institutions and researchers are anxious to work with the public to help identify pets and their owners and to help insure that only stray dogs become involved in research.

Krevans said that issues of inhumane treatment of animals or the use of animals for capricious research obscured the issues behind the pending legislation. "If the concern is that animals are used capriciously," concern should hone in on those specific cases rather than advancing support that would suppress legitimate biomedical research.

Saul J. Robinson, clinical professor emeritus of pediatrics at UC—San Francisco, referred to the continuing treatment required by young Lamb, and said, "there is no doubt in my mind, with all sincerity, that these things would have been hindered and probably would not have been possible without animal research." Robinson has been Lamb's cardiologist for nine years.

Also opposing the legislation, and pointing to their own survival as a testament to the value of animal research, were heart transplant recipient Cynthia Jelkman, 26, of Los Angeles, and Charles Walker, 32, of Mountain View, who was Stanford's second heart—lung transplant patient.

"I see the entire bill as an atrocious mistake," Jelkman said. She referred to what she called the wastefulness of breeding dogs specifically for the laboratory, while nationally, 15 million unwanted dogs and cats are killed annually in pounds.

Emphasizing that research is an ongoing, constantly evolving activity, Walker said, "they could not do anything for me until I was 13 years old." He noted that research has now made treatment possible at a much earlier age for many people born with heart defects.

STANFORD NEUROLOGISTS TURN OFF IMMUNE DISEASE AT THE SOURCE

STANFORD—

Researchers at Stanford have moved one step closer toward their goal of turning immune diseases off at the source by learning to genetically control the symptoms of a chronic disease of the nervous system.

Although his work has focused on a disease in mice that mimics myasthenia gravis, Lawrence Steinman, assistant professor of neurology, said that other diseases linked to the immune system—such as multiple sclerosis, juvenile diabetes, and rheumatoid arthritis—might be treatable in the same way.

Graduate student Matthew K. Waldor, Subramaniam Sriram, research associate, and Hugh O. McDevitt, professor of medicine/immunology, collaborated with Steinman on the study published in the May *Proceedings of the National Academy of Sciences*.

The fatigue and weakness in muscles of the eye, face and throat that are symptoms of myasthenia gravis, are thought to arise from an overactive immune system. In healthy patients, nerve cells relaying messages from the brain to muscles use several chemicals to transmit the message between cells. The protein on the muscle that recognizes and "receives" one of these chemical messengers, called acetylcholine receptor, or AChR for short, plays a central role in myasthenia gravis.

Because of a defect in their genes, the 8,000 Americans who have myasthenia gravis produce antibodies that destroy the terminals that receive acetylcholine in the muscles, short—circuiting the body's electrical system and triggering disease.

Conventional treatments for the illness act by increasing the number of receptors available, or by slowing their breakdown. But Steinman and his team have found the gene in mice that "tells" cells in the immune system to produce the offending antibodies. Going one step further, they have developed tailor-made proteins, called monoclonal antibodies, that latch onto such genes and turn them off, much like turning off a faucet.

In the mice studied, once the "faucet" was turned off, normal cell communication returned, and the symptoms of myasthenia gravis disappeared.

-more-

7-25-83

The next step is to attempt the same sort of disease regulation in non-human primates, Steinman said, before any testing in humans might be done. Even after studying the mice for up to a year after the experimental treatment, no negative side effects have been detected, Steinman said, though toxicity will continue to be closely followed in further research. Primate studies are scheduled to begin in Europe and the United States within the year he said, perhaps prompting studies in human patients within three to five years.

Prednizone, a steroid that induces a blanket suppression of the immune system is one of the current popular treatments for myasthenia gravis, that "work quite well," Steinman said, though side effects such as high blood pressure, weight gain, and increased vulnerability to infection make the drug less than ideal.

But another disease linked to an immune defect, multiple sclerosis, has no effective treatment at all, and might be the first target illness to be treated by the new therapy, if animal studies confirm early promise, he said.

In patients with multiple sclerosis, the fatty sheath that provides insulation for nerve cells is slowly eaten away by misguided antibodies.

For twenty years, scientists have searched without success for the mysterious antigens involved in m.s.—protein molecules that send up the alarm in the human body and bring the full power of the immune system to bear against the nerve cells.

"That may be telling us something," said Steinman. "There may not be a specific m.s. antigen, but instead a variety of antigens that trigger the disease. We've taken a different tack and decided that if we're not going to get anywhere looking for the antigen, let's take the next available clue and try to devise a therapy for the disease based on that clue."

The "clue" Steinman speaks of is the gene that scientists have identified that serves as a blueprint for the offending antigen. Identifying and "turning off" the gene would permit physicians to focus on the specific, defective part of the immune system that instigates disease, rather than suppressing all aspects of the body's ability to fight infection.

"It's a new and different type of immune regulation," said Steinman. "There's no certainty that it will work in humans, but it could be a major change from the fairly brutal types of immunosuppression that have been done in the past—hit the immune system with a crude chemical sledgehammer and hope for the best."

A BIOTECH RACE TO BUILD A BETTER BUG

STANFORD—

Forty years ago, harnessing tiny organisms to produce needed chemicals meant grinding up bread mold and extracting a crude rendition of penicillin, the miracle antibiotic of the 1940s. Last week, 300 scientists from 17 countries gathered at Stanford University Medical Center to discuss their increasing ability to reach inside the genetic machinery of live bacteria, where they can manipulate a few chemical "gears" to produce precisely the product they want for use in medicine, industry and agriculture.

Though commercial production of such chemicals has been relatively slow, the scientists who came to compare their growing list of biochemical tools predicted that a new bacterial friend, *Bacillus subtilis*, may speed the process considerably, perhaps producing its first commercial products within the year.

Long used in the fermentation industry in production of food and detergents, *B. subtilis* and other members of the *Bacillus* family are now giving *Escherichia coli* a run for its money as the favorite slave of genetic engineers.

"These soil bacteria are amazing creatures compared to *E.coli*, especially when one looks at the diversity among the *Bacillus* bugs," said A. T. Ganesan, the Stanford professor of genetics who organized the second international conference on the genetics and biotechnology of *Bacilli* together with James A. Hoch of Scripps Clinic in La Jolla.

"We have not even touched the surface in terms of exploiting the useful characters of these organisms in the fermentation industry, in breaking down proteins and other compounds in the soil, and in the production of antibiotics," said Ganesan, who has studied the genetics of the bacteria for 25 years. "The bugs will also have an important role to play in the production of safe insecticides and in improving cereal crop production," he said.

"It's important for any company that wants to stay on top in this field to place part of its bet on *B. subtilis*," said Tom Parmeter, the president of Syntro Corporation, the La Jolla biotechnology firm that co-sponsored the conference.

Potential advantages of *B. subtilis* over *E. coli* are four fold:

- *B. subtilis* normally secretes the proteins it makes, whereas *E. coli* keeps most of its product inside the cell. Currently, even if they can force *E. coli* to produce a desired product, scientists must burst (and hence kill) the cells to get it out after a fairly complicated filtering process, whereas the protein products of *B. subtilis* can be harvested without disturbing the bacterial colony.
- Unlike *E. coli*, *B. subtilis* grows best in soil and moldy hay, and can't survive in the human body. Hence, even the remote risk that a runaway bug might trigger human illness is extremely small.
- The membrane coat of *E.coli* is studded with chemicals that can be toxic to humans, and must be carefully removed in productions of any medicines. *B. subtilis* does not carry such toxins.
- Several strains of *B. subtilis* lack cell walls, and therefore might provide a good source of digestible protein for human or animal consumption if they were produced in large quantities.

That's the good news. The bad news is that, up until very recently, researchers have had a tough time coaxing *B. subtilis* to incorporate foreign genes into its DNA. Enticing the organism to "overproduce" proteins that it was born to make has already been accomplished, but prompting it to produce desirable foreign proteins, such as insulin or interferon, has proved a much greater problem. In addition, *B. subtilis* produces enzymes that can "chew up" the desired protein before it can be extracted from solution. Several speakers at the conference reported encouraging progress along these lines in the race to build a better bug

Vasantha Nagarajan, a researcher for Genex, a firm based in Gaithersburg, Maryland, reported her firm's ability to identify, clone and transplant into *B. subtilis* a gene that codes for "subtilisin," an enzyme used in the detergent industry to break apart unwanted proteins.

By stuffing multiple copies of the gene into each bacterium, the Genex researchers were able to increase the organism's production of the enzyme by 200 fold. "I'm sure we can increase the yield even more as we optimize conditions," Nagarajan said. "This was just a preliminary test to see if the procedure worked."

"Our method is very powerful," she said. "We were surprised and delighted that it worked."

Using a different procedure, which was also recently patented, James Wells of Genentech, a South San Francisco biotechnology firm, produced similar results. Industrial researchers are not as excited by the method as a new way to make subtilisin (plenty of the enzyme can already be made cheaply by conventional means) as they are about its potential as a model for producing scarcer proteins, said Wells.

-more-

3-3-3

The key to both the Genex and Genentech findings, was the identification of a "promoter" and "signal sequence" that regulate production of the gene, he said. A promoter is a segment of DNA that controls the amount of protein each gene produces, while the signal sequence is an adjoining bit of DNA that allows the protein to escape the confines of the cell. Researchers around the world are racing to identify and clone a good promoter and signal sequence from closely related bacteria that can be spliced to foreign genes and interpreted within *B. subtilis*. This task is difficult because, unlike *E. coli, B. subtilis* is a very sensitive detector of alien DNA. Like a tourist who can't speak the native language, foreign DNA is left without an interpreter within the host cell. And if the message is not interpreted, no new protein can be made.

Mervi Sibakov, from the University of Helsinki, described similar efforts to construct an all-purpose bit of DNA that could prompt production of a wide variety of proteins. The Finnish group was successful in coaxing *B. subtilis* to produce three compounds valuable in the production of antibiotics, though the yield of each compound was very low. Nonetheless, their data fed the flames of enthusiasm over the potential use of the organism in industry.

Shing Chang, a scientist at Cetus corporation whose interest in *B. subtilis* centers on the production of human growth hormone and other compounds for medical use, is optimistic about the organism's potential value.

None of the hurdles discussed at the meeting are insurmountable, said Chang, who predicts that commercially viable compounds, produced by inserting mammalian DNA into the bacteria, may be possible within one year.

VOLUNTEERS HELP CREATE POSITIVE EXPERIENCE FOR CHILDREN IN HOSPITAL

STANFORD—

Sue Emerson works four days a week as a programmer analyst at NASA-AMES. The fifth day, she volunteers at Stanford University Hospital (SUH), spending the morning playing with the children in the pediatrics playroom.

Seventy-one-year-old Evelyn Parsons has been coming to the playroom one morning each week for the last 10 of her 21 years of volunteer work at SUH. She's often told herself it's time to retire, but, she said, she just can't seem to tear herself away from the children.

Like most Silicon Valley engineers, Gary Elston's work week is rarely limited to 40 hours. Yet one evening each week, he too volunteers at the playroom.

Self-sacrificing? Perhaps. But these are just three of more than 60 hospital auxilary members, Stanford students, and candy stripers who donate their time to work in the pediatrics playroom, the most opular volunteer service at the Hospital. It's more than the natural appeal of children that accounts for their willingness to work there. Something special happens in the playroom, many volunteers say—something they'd be reluctant to miss out on.

"Most of the kids are pretty unhappy because they're in the hospital," said Jennifer Gray, a recent graduate of Palo Alto High School who's worked at the playroom for about a year. "Your goal is simply to make them laugh. If you can let down your guard, and act like kids, it really helps. If you can just make them smile, you're flying high."

"As many as 44 children, from birth to age 18, are on the unit at any time," said Collette Case, the recreational therapist who supervises the playroom and the play therapy program that includes it, as well as community education, inservice training for other health professionals, training for recreational therapy students, and networking with other health care agencies. "Their illnesses are usually pretty acute. The goal is to make their stay in the hospital a positive, growing experience."

In addition to the volunteers, Case is aided in achieving this goal by two other recreational therapists, Ellen VanderWilt, and Betty Lovelace, who developed the program nearly 10 years ago.

"We try to give a feeling for the sights and sounds of the hosptial, and introduce the different people children are likely to meet," Lovelace explained.

It starts on Sunday afternoons, when the therapists show children scheduled to enter the hosptal slide show that takes them from admission to discharge. They also take the children on a walking tour of the hospital. And with a miniature hospital, puppets, and medical equipment, the therapists encourage the children to play out their experiences so they can grow more comfortable with them.

-more-

During the children's stay in the hospital, the playroom is the one "safe" place for them, Case explained. "The children can relax here. They know no procedures will be done here, so they feel they can talk about their fears and concerns. Often, children will do things in here, such as walk, or use an injured arm, that they won't do elsewhere. The playroom is therapeutic for them."

It's not just therapeutic, the playroom is a child's dream. Toys—most of which are donated by parents and community groups—are piled along the walls. Video games are available for the asking. A pool table occupies a large area, and an outdoor courtyard bears murals of forests filled with animals. The volunteers answer to nearly any whim, and the children are encouraged to play with one another as well.

"We try to concentrate on the wellness of the children, and make the most of what they can do rather than focus on their limitations," Case said. It's often necessary to point out the wellness to the parents also, she added.

The children derive a lot of support and encouragement from one another. "We once had a boy who was an amputee," Case recalled. "He had a hard time dealing with it. Now he comes back often to visit other children and encourage them."

Much of the interaction with the children is on a one-to-one basis, Case said, in order to maximize their socialization and growth development considering their individual health status. Organized group activities are often held to help out individuals as well. "We have lots of parties in addition to regular holiday and birthday parties," Case explained. "If someone isn't eating well, for example, we'll have a cooking party."

Despite the appearance of just fun, there's a lot of subtle therapy that goes on in the playroom, Case pointed out. And this makes the selection and training of volunteers especially important.

Many applicants initially request the playroom because of their love for children, Case said. But once they get through the two interviews and orientation sessions, they realize they may not be able to handle dealing with sick children. Even the ones who do end up working with the children, Case continued, are susceptible to "burnout."

"I was a bit hesitant at first because the children are so sick," Parsons recalled. "But you get attached to so many, and when you see them getting better, it makes it worthwhile."

Elston's commitment includes bringing a box of toys with him since the playroom's toys are locked up in the evenings when he comes. Even with his dedication, however, or perhaps because of it, he finds working with the children difficult at times.

"I had to stop coming for about three weeks once, because it just got too intense," he admitted.

But Elston and the other volunteers stay on at the playroom in spite of any problems the work may create.

"When I was young I had to spend some time in the hospital," Emerson recalled. "I know how much it helped to have people to talk with, to play with, and to pay attention to me. I'd like to do the same for these children."

VOLUNTEERS NEEDED FOR CLINICAL TRIALS

STANFORD—

Volunteers from the community are being actively sought by Stanford University Medical Center to participate in the clinical studies of three separate research efforts.

The studies pose questions ranging from the effects of different level exercise on sedentary men, to the effectiveness of various blood pressure drugs, to the results of hormone replacement therapy in postmenopausal women.

Details regarding each research project and the types of volunteers they need follow.

Healthy, sedentary men between 40 and 60 years of age are needed to volunteer in a three-month study designed to compare the health benefits of low and high level exercise.

"Especially in sedentary people, low level exercise will produce the same training effects as high level exercise—it just takes a little longer," believes Dr. Robert DeBusk, director of the Stanford Cardiac Rehabilitation Program.

To confirm this, the three-month study will examine how slower paced activity like brisk walking compares to rigorous exertion such as running or swimming in contributing to cardiac health.

The study will involve three randomly-assigned groups of volunteers. One group will carry out their usual activities (control group); another will carry out low level exercise training such as brisk walking; and the third group will perform high level exercise training such as jogging.

Portable heart rate monitors will be used to help volunteers maintain the appropriate intensity of exercise, and individualized instruction will be given concerning the amount and duration of exercise training.

After initial telephone screening, volunteers will undergo a preliminary evaluation including medical history, physical examination, treadmill exercise test and measurement of blood fats. Participants will repeat the treadmill test at six and 12 weeks and will be asked to record their food intake and physical activity. They will also wear a heart-rate recorder at specified times during the study.

-more-

One potential benefit of participation in the project is thorough screening for latent (unrecognized) cardiovascular disease. Jeff Martin, a recent participant in a related pilot study for this project, said he was motivated to take part after a close relative died suddenly of heart failure. "My goal was really to find out if my heart was strong. I feel more comfortable now knowing that there's probably nothing to worry about."

On completing the study, which is funded by the Pepsico Foundation, participants will be given an individualized "prescription" for ideal long-term exercise conditioning.

Participants must be free of cardiovascular disease and cannot have participated in any sort of regular exercise program for at least three months prior to the study.

Those interested should call the cardiac rehabilitation program at (415) 497-6461 during regular business hours and ask for the "coordinator of the high/low study."

* * * * * *

Volunteers between the ages of 20 and 70 are needed to participate in studies to confirm the effectiveness of three different anti-hypertensive medications.

The drugs, which have already been through animal trials and clinical testing in Europe, offer potentially promising ways to treat high blood pressure, according to principal investigator Dr. Peter Rudd, assistant professor of medicine at Stanford.

Each study preparation will be compared to either a placebo or a similar medication already on the market. The three separate studies are based at the Veterans Administration Medical Center in Palo Alto.

Volunteers are needed who have mild to moderate high blood pressure, and are willing to come in as often as weekly for blood pressure monitoring. Two of the studies last three months, and the third lasts a year.

Participants will be offered free comprehensive medical evaluations at the beginning and end of the studies. Screening and follow-up laboratory tests will include urine, blood, electrocardiogram, and chest X-ray. Volunteers will also receive reimbursement for travel and any worktime missed.

-more-

3-3-3

Rudd said he and co-investigator Dr. Keith Marton, assistant professor of medicine, expect to demonstrate that the new medications are more effective with fewer side effects than those standardly used to control high blood pressure.

Anyone interested in volunteering or obtaining further information should call Valerie Vierra, R.N., at (415) 493-5000, ext. 5918, weekdays from 8 a.m. to 5 p.m.

. . . . . .

Volunteers are being sought for a study to evaluate the effectiveness of hormone replacement therapy for postmenopausal women.

The researchers, headed up by Dr. Leroy Heinrichs, chairman of the department of obstetrics and gynecology, are recruiting women who are at least 47 years old, and are at least one year postmenopausal. The women should not have received hormone replacement therapy in the past six months. Women who have had hysterectomies, or who have their uterus intact are eligible.

Specifically, the investigators plan to study the effects of estrogen, estrogen with progesterone, and estrogen with testosterone on psychological factors such as mood changes. They plan to study the effects on physiological variables as well.

Participants will receive laboratory tests and medication free of charge, and those who complete the one-year study will be paid a stipend.

For further information, contact Dr. Jean Dixen at (415) 497-2432.

VOLUNTEERS NEEDED FOR STUDY ON DIABETES AND SEXUALITY

STANFORD-

Female volunteers are needed for a study investigating whether diabetes affects sexual response, said Dr. Diane Morrissette, a visiting scholar in Stanford University School of Medicine's department of physiology.

The study will involve insulin-dependent diabetic women, between 21 and 43 years of age, in four one-hour sessions which can be arranged to fit the individual's schedule.

Volunteers will be provided with results of laboratory tests measuring hormonal levels in the blood.

For more information, contact Morrissette at (415) 497-2432.

COMMITTEE ON WELL-BEING PLANNED IN DEPARTMENT OF OBSTETRICS AND GYNECOLOGY

STANFORD-

The chairman of the Stanford University department of gynecology and obstetrics has agreed to participate in a faculty-resident-staff committee being formed to deal with internal difficulties highlighted by a controversial memorandum.

Toni McCain, a resident in the department, said Friday that she and two colleagues had agreed to help form the committee at the suggestion of university officials, including Dominick Purpura, dean of the Medical School. The three omen physicians had sought support from the president and dean after one of them, chief resident Zena Levine, was the recipient of a July 21 memo from department chairman LeRoy Heinrichs.

The memo, copies of which were sent to department faculty, chief residents and several administrators, noted that Levine was pregnant and requested that she postpone a planned vacation for scheduling reasons.

The memo, rescinded by Heinrichs and the university, contained material which Heinrichs in an Aug. 6 apology noted was "offensive to many."

The original memo stated in part:

"Pregnancy can also ultimately affect patients who must bear the frustrations of your colleagues who must work with you or those who remain in your absence. Some faculty members express the modern view that responsible career women do not risk incurring the age-old criticism of women as unreliable professional colleagues, and some advise me, for that reason, to appoint no more women as residents in this program."

Purpura called the memo, which was released by an unidentified person to

-more-

members of the news media, as "highly inappropriate, offensive, insensitive, and most importantly, unusable."

Heinrichs has apologized to the resident and her colleagues, and both he and Purpura have reaffirmed the school's desire to uphold Stanford's policy of affirmative action in the hiring of women.

Heinrichs noted that under his leadership, half of the department's 18 residents are women, consistent with current national trends.

He said the intent of requesting the change in vacation schedule was prompted by a desire to ensure that adequate medical staff was available and avoid placing a burden on residents already busy, a problem endemic to residency programs.

McCain, Levine, and a former chief resident now in private practice, Barbara Peters, had asked both Purpura and university President Donald Kennedy to take action.

Purpura asked that the residents initiate a committee to help deal with departmental tensions.

Departmental committees on well-being have become common at Stanford Medical School in recent years. McCain has prepared an invitation to residents, faculty and staff to participate in the proposed committee. Heinrichs has said he would sign and distribute the letter.

"This is an invitation to participate in a new approach to intradepartmental communication and problem-solving," says the proposal drafted by McCain. Committees "are intended to be frank and open sessions where pertinent facts on particular issues are presented and suggestions are made which lead to real solutions."

"This (the committee) certainly has the potential to be useful," Levine said Thursday.

Peters, who has a clinical faculty appointment pending, said "open discussion through a committee is a powerful antidote to potential misunderstandings."

WEIGHT CONTROL PROGRAM BEGINS NEXT MONTH AT STANFORD HOSPITAL

A weight control program, to be conducted by registered dietitians from the department of dietetics at Stanford University Hospital, will be held Sept. 27 through Nov. 29.

The course is open to the public and will take place Tuesday evenings at the Hoover Nursing Cottage.

Highlights of the program include a personalized weight loss plan, low calorie cooking demonstrations and snacks, menu planning, behavior modification techniques, and a dining out experience.

Kristine Birge and Patricia Kearney, registered dietitians at the hospital, will conduct the classes. Guest speakers will include Dr. Mary Southam of the Behavioral Medicine Program at Stanford, and Elad Levinson of hospital Human Resources Development.

"We want to show that there are safe and healthy ways to achieve weight control," said Birge, "while making the experience an enjoyable one with group discussions and active participation."

Many of the instructional materials developed for use in the course will be used by the dietitians in patient care programs as well, she said.

Enrollment in the "Enlightening Experience" program is limited to 20 participants. Early registration is advised. For more information, call Birge at (415) 497-5440.

DIOXIN USED TO TEASE APART CANCER CAUSES

STANFORD—

While U.S. lawmakers and physicians debate the human health risks of dioxin, James P. Whitlock Jr., a pharmacologist at Stanford University Medical Center, is using the chemical to explore, on a genetic level, how some people are able to disarm the same toxic compounds that cause cancer in others.

Dioxin, also called TCDD, has been controversial around the world, as a contaminant in "Agent Orange," an herbicide used as a defoliant during the Vietnam war. Industrial accidents and improper disposal of the compound in communities in Missouri and Italy have frightened citizens into fleeing their homes.

The chemical can be potently lethal, but there is great variation among animal species in their susceptibility to toxicity. Despite recent public concern about possible long term effects of exposure, the only consistent and well-documented symptom in humans accidentally exposed to dioxin has been a temporary, severe form of acne, Whitlock said. Scientists still have only a murky understanding of how the chemical causes changes inside humans and animals.

At a recent meeting of the International Union of Biochemistry held at Stanford, Whitlock, an associate professor of pharmacology, described the ways dioxin affects an enzyme system commonly used by most animals and man to process large molecules that might otherwise get caught and cause harm within the body.

Usually, such enzymes are useful in helping the cell eliminate potentially dangerous compounds. But occasionally the enzymes are more hindrance than help.

Whitlock studies "benzopyrene," a common environmental carcinogen found in auto exhaust, industrial emissions and cigarette smoke, as it moves into cells and is broken apart and recombined into cancer-causing components.

-more-

8-23-83

"Many compounds, like benzopyrene, aren't themselves carcinogenic," Whitlock said, "but during their metabolism within the cell they may be activated to metabolites that are active carcinogens. We're interested in those enzymes and in how the cell deals with foreign compounds."

Whitlock and his colleagues have used biochemical tools and genetic tricks to track the chemical's movement inside the cell. Chief among their tools is dioxin, which induces an increased production of the enzymes that process benzopyrene into both harmless metabolites and harmful cancer causing compounds.

By isolating several mutant strains of cells that don't respond to dioxin, and comparing them with cells that do, Whitlock has begun to understand how genes regulate the production of the enzymes. His studies have revealed a nuclear protein which "recognizes" dioxin and acts as a "switch" to turn the enzyme gene on and speed production of both beneficial and harmful enzymes. Currently Whitlock is trying to pin down exactly how this "dioxin receptor" controls production of each type of enzyme.

Although Whitlock's studies have been conducted with liver cells from mice, the enzyme systems also play an active role in humans and may serve as a good model for the way chemicals may act in concert to cause human cancers, he said.

"It's not at all clear what the effects of dioxin are on humans," he said. "There has been a lot of hysteria, but what we need to do is to find out exactly what's going on inside the cell."

FORMER PREEMIES TO REUNITE!

Editors note: Members of the news media are invited to attend and cover this weekend event. Please call the news bureau at the above number if you plan to come.

STANFORD—

Former patients of the Intensive Care Nursery at Stanford University Hospital will be reunited at a party, from 1-4 p.m., Sunday, Sept. 11, in the hospital's garden patio.

Children who were hospitalized in the ICN as premature or critically ill infants—as far back as 1978—and their immediate family members are invited to attend the afternoon event. Food, games and entertainment (including clowns) are planned.

The reunion, intended as the first of an annual event, is sponsored by the Stanford University Hospital Auxiliary. Families planning to attend should respond as soon as possible at (415) 497-7200, an answering service. Please leave a message as to the name and number of family members coming.

For further information about the reunion party, call (415) 497-5480.

STANFORD—

Stanford University Medical Center has been given state approval to resume a renal (kidney) transplant program.

Dr. Rex Jamison, professor of medicine and chief of the division of nephrology, said kidney transplants—initially about 25 to 30 annually—could begin here in about a year. A renal surgeon and transplant nephrologist will be recruited, he said.

SUMC was notified earlier this month by the Office of Statewide Health Planning and Development that a Certificate of Need (CON) had been granted for the project.

To receive a CON to begin or resume certain medical services, institutions must prove that they are medically and financially sound, and fundamentally, that the project fulfills an area health care need.

Patricia Stone, a Stanford health care planner, noted Friday (Aug. 19) that the Santa Clara County Health Systems Agency had waived its review of the application, filed March 30, enabling the state to reach a decision quickly and without public hearings.

Cost of the project is about $18,000 for therapeutic equipment, and no construction is planned, Stone said.

SUH had a renal transplant program between 1965 and 1971, and then the specialized program became inactive.

Jamison noted that recent developments in immunosuppressive drugs—needed to prevent the body from rejecting the foreign organ—have increased survival of transplanted kidneys.

In its CON application, Stanford noted that currently no renal transplant program exists in Santa Clara County, where more than 80 persons under age 50 were waiting for new kidneys. Currently these persons must seek transplantation at centers outside the area, Jamison said. In northern California, the only existing renal transplant facilities are at the University of California at San Francisco and Pacific Medical Center, San Francisco. Both of these institutions are experiencing long waiting lists, Stanford said in its CON application.

The transplant program will be a joint venture between Stanford University's department of surgery and the department of medicine's nephrology division.

Stanford's existing nephrology program includes a hemodialysis unit, where about 40 patients undergo regular maintenance dialysis.

Other Stanford transplant programs include hearts, heart/lungs, corneas, and within a few years, bone marrow.

MONOCLONAL ANTIBODIES AND CANCER TREATMENT: AN OVERVIEW

STANFORD—

In 1980, a 67 year-old man agreed to undergo a new experimental treatment for a rare lymphatic cancer that was killing him.

Previous treatments with conventional and experimental drug therapy couldn't halt the disease that was slowly ravaging his liver, spleen and lymph nodes. But after a four-week regimen of "monoclonal antibodies," specially created protein "bullets," the cancer began to recede.

Today, more than two years after treatment, the man remains completely free of the disease.

The early success triggered hope in scientific circles and the general public that monoclonal antibodies, already valuable as tools to diagnose disease and detect cell differences too tiny to be seen any other way, might have a new use in eradicating cancer. Two years and several patients later, Ronald Levy, the Stanford oncologist who pioneered the new treatment, describes his results as "encouraging," though he cautions that it is still too soon to tell precisely what role the specialized antibodies will play in thwarting which types of cancer.

Monoclonal antibodies were first developed by researchers George Kohler and Cesar Milstein in Cambridge, England in 1975, as a variation of the normal antibodies that every mammal produces to attack any foreign substance—virus, bacteria, or cell—that invades the body.

Each antibody is designed to precisely match a specific site on the invader's surface and to latch onto it like a key in a lock. Once the antibody and foreign substance are joined together, other cells of the immune system are alerted to join the battle and kill the invader.

A wide variety of slightly different antibodies may be produced in response to a typical infection, but Kohler and Milstein developed a method of screening the mixture to select and harvest only the specific type of antibody they desired and produce it in large amounts.

Levy and other researchers have capitalized on the specificity of the monoclonals to develop a potentially powerful treatment for some types of cancer.

To produce the antibodies they use in treatment, Levy and his colleagues first inject mice with cancer cells filtered from a blood sample of the patient to be treated. A few days later, they remove the mouse's spleen, which now contains large numbers of white cells, the blood-borne factories where infection fighting antibodies are produced. Some of these white cells have been become sensitized to the injected cancer cells, and will produce antibodies that can specifically seek out and destroy cancerous cells in the patient's body without harming healthy tissue.

-more-

The scientists then fuse the white cells in a laboratory dish with cells from a mouse tumor, creating a new, immortal cell line or "factory" that can produce large quantities of the desired antibodies.

Currently, it takes Levy's team an average of six months to produce enough antibody to treat a single patient, at a cost of approximately $50,000. If and when the experimental procedure is proven effective within the next couple of years, private companies could take over the production of the proteins on a large scale, and greatly reduce the treatment cost, Levy said.

All 26 patients that Levy has thus far treated with monoclonal antibodies have suffered from one of several specific types of lymphoma and leukemia. He said the reasons for limiting the treatment to lymphoma and leukemia are primarily two-fold: as cancers that float through the bloodstream, lymphomas and leukemias are relatively easy targets for the special treatment, in comparison to solid tumors.

In addition, because leukemias and lymphomas are cancers of the immune system, they have been well studied. "We know a lot about these tumors because we know a lot about the immune system and the cells that make antibody," Levy said. "So it made sense that lymphomas and leukemias would be the first thing to start working on."

Other universities and research institutes across the United States have begun to explore the use of monoclonals on "virtually every kind of cancer," Levy said, though none of the programs have yet developed to the point of accepting patients.

"We really don't know what the final role of monoclonal antibodies will be in the total treatment of a person with cancer," Levy said. "I don't think that they will ever replace the current therapies that really do work, but I do think that they will be useful, probably in an adjunctive role."

While Levy has used the antibodies alone in treatment, other researchers are investigating the possibility of tagging the proteins with a radioactive isotope or chemical poison which they could aim exclusively at the cancer cells, sparing the healthy tissue that is inadvertently killed through conventional cancer treatments.

"Eventually we hope to add monoclonal antibodies to the other modalities of treatment we have," Levy said, "to be used in different combinations, depending on the needs of each individual patient."

ARMAND HAMMER DEDICATES $500,000 CANCER LAB

STANFORD—

A $500,000 gift from industrialist Armand Hammer will help expand and finetune the promising new use of specialized protein "bullets" that harness the human immune system to battle several types of cancer, said Ronald Levy, Stanford cancer researcher, at a news conference at Stanford Medical Center Thursday (Aug. 18).

Hammer joined Levy at the conference, called to dedicate the expanded laboratory funded by the Hammer gift.

"We've had some preliminary results that are very promising, and Dr. Hammer's gift will help us expand our laboratory facilities and move a lot faster to test the possibility of making this into a therapy that we hope eventuallly can be made available to large numbers of patients," Levy said.

In 1981, Levy, an associate professor of medicine/oncology, used the special proteins, called "monoclonal antibodies," to treat a 67-year-old man dying from a rare form of lymphatic cancer. Today, more than two years after completion of treatment, the man is completely cancer free.

Encouraged by the early results, Levy's team turned their attention to developing antibodies against similar cancers in other patients. Four more patients have completed the treatment, and the scientists have begun the six-month-long process of manufacturing the custom-tailored antibodies for eight more patients. The results have been "encouraging" Levy said, though it is still too soon to tell exactly how successful and how generalizable the results will be.

"We're finding that the more sharply the antibody can distinguish between normal cells and tumor cells, the better effect we can get," Levy said. "And the best distinction between tumor cells and normal cells is attained by making a different antibody for each patient. That's a long and laborious process."

The new laboratory space will permit an expansion of staff who can seek ways to streamline the production of antibody, to build on the current knowledge and treat more patients more effectively, Levy said.

The focus of his research now is in identifying the "target" that the antibody bullet uses to home in on cancer cells and lead to their destruction, he said. Currently, such targets have been identified for only a few specific types of lymphomas and leukemias, but researchers around the country are seeking such targets for other types of cancers, he said. "When people understand what those other targets are, then we'll know how to make antibodies against them."

"I know that the work done in this laboratory will fully justify my faith in Dr. Levy and his colleagues and measure up to the finest standards of the Stanford Medical Center," said Hammer. "Much fine work has been done at Stanford in the past, and I know the future will continue in that great tradition."

"This is only one step in the work that has to be done in the path to finding a cure for all cancers," said Hammer, who recently established a $2 million fund to support research towards a cancer cure. "But I think it is an important step."

NEWS CONFERENCE CALLED TO DEDICATE NEW CANCER LAB

STANFORD—

Armand Hammer, chairman of Occidental Petroleum and head of the President's Cancer Panel, will join Stanford cancer researcher Ronald Levy at an Aug. 18 press conference to dedicate a new $500,000 laboratory.

The informal press conference, to be held at 10 a.m. August 18 in Room TE 110 at Stanford University Medical Center, will be followed by a press tour of the facility which was funded by the Armand Hammer Foundation of Los Angeles.

Levy and his colleagues are expanding their study of "monoclonal antibodies," special proteins of the immune system that can seek and destroy cancer cells in the body without damaging healthy tissue.

"The research is promising," said Levy, "and the rate limiting step has been lab space. Both Dr. Hammer and I have been anxious to expand the work."

Earlier this year, Levy was named the first beneficiary of an annual $100,000 prize established by the Hammer Foundation to reward "the first person or persons deemed to have made the greatest contribution to the cure for cancer."

Levy shared the prize with British researcher George Telford Stevenson, for their experimental adaptation of antibodies—infection-fighting proteins of the immune system—to devise a new, experimental treatment of cancers of the blood and lymph glands.

First developed in England in 1975, monoclonal antibodies are proteins made by biological factories that the scientists construct by fusing cells of the human immune system with a cell from a mouse tumor. Inheriting characteristics from both parent cells, the new "factories" can produce large quantities of identical antibodies that can be injected into the bloodstream to specifically kill the cancer cells.

Early results on the effectiveness of the treatment in fighting some leukemias and lymphomas have been "encouraging," Levy said, but it is still too soon to tell precisely what role monoclonal antibodies, already valuable in research, will eventually play in cancer treatment. The news conference is designed to permit an informal question and answer session on Levy' ongoing research. No new, unpublished data is expected to be reported.

Room TE 110 is on the first floor of the Psychiatry and Behavioral Sciences Building, located at the northwest edge of the medical center.

OPERATING BUDGET APPROVED FOR STANFORD UNIVERSITY HOSPITAL

STANFORD—

The Stanford University Board of Hospital Directors approved Wednesday (Aug. 10) a 1983-84 net operating budget of $174.4 million for Stanford University Hospital (SUH).

The board also approved a capital budget of $5.3 million. Major projects earmarked for the fiscal year beginning Sept. 1 are a renovated intensive care unit, $500,000; relocation and modernization of the tissue typing lab, $250,000; and modernization of the radio page system, $250,000.

The budget is based on projected net revenues of $182.9 million, which reflect an average price increase of 8.4 percent, said Sheldon King, SUH director and executive vice president. The revenue figures include $3.3 million for contingencies and future capital improvements.

Less than 1 per cent of the increase has been earmarked for the hospital modernization program, the project expected to bring the hospital up to modern standards in coming decades, King said.

Ancillary services, which account for 60 percent of the hospital's revenue and include all services (such as X-ray, operating room, drugs) except the basic room rate and professional fees, will increase an average of 7.5 percent effective Sept. 1.

Room rates, one of the largest single items for which hospitals must charge, will rise an average of 9.7 percent. Typical daily increases are from $205 to $225 per day for a well newborn baby; from $350 to $384 for a semi-private room for most medical/surgical patients receiving the services of housestaff. The highest rates—for a handful of patients receiving the maximum level of intensive care—will rise from $1825 to $1995 per day. (Forty separate rates are in effect).

Last year, SUH raised room rates 5.9 percent on May 15 and 13 percent on Sept. 1.

King said that while room rates are increasing, there is a mitigating tendency for the rooming portion of a patient's bill to decrease, because the average length of hospital stay is declining gradually.

"In past decades, when hospital care tended to be custodial, we charged patients for the room and hoped they got better," King said.

"Every year we are able to offer more specific services, which, realistically, result in higher costs.

"Hospitals are more vulnerable to inflation and rising costs than other segments of the economy," King said. "We cannot forego a new development or innovation simply because it is expensive. We must constantly keep pace, and our costs escalate even if the consumer price index remains relatively stable."

Despite economic pressures, King pointed to an ongoing cost reduction program which is expected to save the hospital $5.2 million in the next fiscal year. Areas targeted for savings include conservation of materials, inventory control, and selected cutbacks through attrition of personnel in areas now functioning with greater efficiency.

NEW FELLOWSHIP FOR KIDNEY RESEARCH HONORS LONGTIME CONTRIBUTOR

Editors: Photos of Dr. Shemesh at work, as well as last week's ceremony, are available upon request.

STANFORD—

An Israeli citizen from Iraq has been named first recipient of the Delano Large Fellowship in Nephrology at Stanford, at ceremonies last week honoring a man who contributed widely to kidney disease research after his son battled renal failure for nine years.

This year's fellowship recipient, effective July 1, 1983, is Dr. Ovadia Shemesh, who received his M.D. at Hadassah Medical School in 1973, and later did research on leukemic tissue culture at the Weitzman Institute in Israel.

As a fellow at Stanford, Shemesh has dealt with many diabetic patients. Now he plans, with Dr. Bryan Myers, associate professor of medicine and director of clinical nephrology, to study patients with either of two types of kidney disease, trying to characterize in a quantitative way how the normal kidney functions and what precisely can go wrong.

The researchers hope, through mathematical analysis of data, to be able to distinguish and thus predict deterioration of the filtration process that characterizes kidney failure. This should help physicians determine early on the potential for thwarting the condition, through appropriate therapies. It should also help them judge the potential role of various new treatments.

Experimental methods involve infusing substances of known molecular size into the patient's bloodstream and, with unique analytic equipment, determining the kidney's ability to clear them from the patient's blood into the urine. The infused substances are meant to simulate proteins—to which diseased kidneys are abnormally permeable, allowing them to leak through into the urine while toxic materials remain clogged behind, causing protein depletion and kidney failure.

"Now that we can recognize the different phases of kidney disease," Myers said at the ceremony, "we will look at the early stages, with an eye towards prevention of renal failure. At least we might be able to prolong an ailing kidney's ability to function.

"This will all take a few years," he added. "But the first two will be the most critical, and with the help of this fellowship, Dr. Shemesh will be able to make important contributions to the research."

Upon completion of his work here, Shemesh plans to return to Israel for a career in academic medicine.

8-8-83

-more-

"The new fellowship serves two purposes," said Dr. Rex Jamison, professor of medicine and chief of nephrology at Stanford. "One is to honor Delano Large's memory; the other is to enable us to continue to train people to try to discover causes and treatments for the disease that felled his son Jeff."

Jamison and Dr. Norman Coplon, clinical associate professor of nephrology, hosted the August 1 event at the Faculty Club.

Large, who graduated from Stanford in 1937 and later received his M.B.A. at the Graduate School of Business, died of cancer on his 69th birthday June 16, 1983, at Stanford University Hospital. He and his wife Jean had become actively involved in fighting kidney disease when their son Jeffrey developed end-stage renal disease at the age of 24 in 1964.

Jeffrey became only the second Californian patient to undergo dialysis treatments at home, after being trained for the procedure by Dr. Belding Scribner, a Stanford alumnus, in Seattle. At that time there were few dialysis centers, Jean Large recalls, and none in this state.

Jeffrey also underwent four kidney transplants, only one of which succeeded—and that one lasted only six months. He spent eight years on hemodialysis, until his death in 1973.

A native of Monterey and longtime resident of Palo Alto, Delano Large helped found a Northern California affiliate office of the National Kidney Foundation, and in 1966 started the Mid-Peninsula Chapter, which is still active.

The new annual fellowship in his name is being sponsored by Satellite Dialysis Centers Inc. of San Jose, a non-profit organization which Large helped found With Coplon in 1973. Initial funding of the fellowship is for 10 years.

Large owned a construction contracting firm which he operated for nearly 40 years. He was helpful in the building phases of Stanford's hemodialysis unit, Jamison recalls.

"Delano Large was a warm, unassuming person, who listened carefully and gave sage advice," said Jamison. "He was a generous man with a fine sense of humor."

Jean Large was active in the Stanford University Hospital Auxiliary for about 20 years, up until this spring.

VOLUNTEERS NEEDED FOR ACNE STUDY

STANFORD—

About 20 volunteers, ages 16 to 30 with moderate to severe facial acne, are needed to participate in a study to test the effectiveness of a new topical treatment.

The three-month, double-blind study will compare a topical preparation of Acutane with another vitamin A derivative which has been used effectively for years in treating acne.

Dr. David Elbaum, a resident in dermatology and principal investigator for the study, said the topical preparation of Acutane is hoped to prove as effective as its recently approved oral form, while avoiding the side effects encountered.

Volunteers must be off any acne medications for at least two weeks prior to joining the study, and then for the duration of the study. They will come in for observation bi-weekly the first month, and monthly thereafter.

Those interested in further information or in volunteering should call Nicole, weekdays at (415) 497-6319.

FOR IMMEDIATE RELEASE

GROUP PSYCHOTHERAPY IN HOSPITALS NEEDS IMPROVEMENT

STANFORD—

Group psychotherapy in many of the nation's general hospitals is a perfunctory function because the technique has failed to keep pace and adapt to the circumstances of the inpatient ward, says Dr. Irvin Yalom, a Stanford University psychiatrist.

This, he adds, has occurred in spite of the demonstrable effectiveness of group psychotherapy in other settings.

"Group psychotherapy makes efficient and effective use of the patients' time and of hospital and staff resources," Yalom maintains. Staff members actively participating in a group therapeutic program feel valued, constructively challenged, and likely to contribute effectively to all aspects of the therapeutic program.

But specialized skills are required for effective leadership, he explains, and not enough professionals are properly trained to function in inpatient psychiatric wards.

"The acute inpatient ward constitutes a radically different clinical setting," Yalom says. "It requires a radical modification of group therapy technique.

Yalom expresses his views in a new book *Inpatient Group Psychotherapy*, 350 pp. Basic Books, New York 1983. The book presents a modified approach and talks about the different ways in which therapists can structure sessions, the kinds of support that should be offered, and the emphasis on the here-and-now—all of which are essential to effective group therapy in hospitals.

For his book, Yalom visited many hospitals. In their psychiatric wards he found groups led without formal sanction. In one ward the medical director, a psychopharmacologist, told him that he had tried to use groups for three months shortly after he had taken over. Having concluded that therapy groups were ineffective in an acute setting, he had dismantled the group program.

"When I interviewed members of his staff," Yalom reveals, "I was informed that the evening nursing staff conducted daily therapy groups concealed under the title 'rap groups.' "

9-30-83 -more-

Unlike outpatient clinics in which one finds group therapy programs to be broadly consistent, in hospital psychiatric wards "there is no coherent body of inpatient group therapy principle and corresponding strategies that are consistent from unit to unit," Yalom reports.

This lack creates a catch-22 situation. "It plays havoc in the education of young psychotherapists," Yalom says, "and encourages a dangerously speculative 'every man for himself/every woman for herself' approach which can be pernicious to the field and to patients' best interests." Moreover, even some university hospitals with the most prestigious psychiatric training programs in the country generally do not offer group therapy training suited to inpatient settings.

Yalom's book describes a group therapy approach which is specifically tailored to the needs of a short-term acute psychiatric ward. His approach involves these key steps:

There must be a realization that goal setting is crucial to the proper functioning of a small therapy group.

Goals must be realistic because if they are overly ambitious they might impair the effectiveness of the group.

The goals of the small group are not the same as the goals of short-term hospitalization.

Some realistic goals for the small therapy group are to engage patients in the therapy process, to help them learn that talking helps, to spot problems, and to alleviate patients' anxiety associated with hospitalization.

"When patients are helped this way, they are motivated to continue to work out their problems in posthospital psychotherapy," Yalom adds.

LASERS IN CARDIOLOGY: DOCTORS ARE HOPEFUL

Editors: Photos available soon upon request, if not included.

STANFORD—

Cardiologists at Stanford University Medical Center are investigating a dramatic new use of lasers for the treatment of vascular disease.

Their initial results from clinical trials of laser angioplasty, as it's called, on patients with blocked blood vessels in the leg, look promising.

"We've been able to re-open clogged vessels in the legs of two patients over the last few months," said Dr. Robert Ginsburg, a clinical assistant professor of medicine in cardiology. "To our knowledge this is the first successful use of laser angioplasty as a treatment for vascular disease.

"Once we feel more comfortable with this technique in diseased legs," he added, "we'll move on to our ultimate goal of attempting the procedure on coronary arteries."

In a report awaiting publication, Ginsburg and co-authors describe the case of a 62-year-old man for whom surgical interventions had failed to correct the problem of severely decreased blood flow in the left leg caused by cholesterol blockages.

The patient had been informed that no further surgery could be attempted, and that amputation was the sole recourse. "This is the only category of patients we're presently performing laser angioplasty on," said Ginsburg, "because they are so severely disabled by leg cramping and pain that we can offer the possibility of some benefit without the chance of doing harm."

Heavy smoking, as well as diabetes, are just two potential causes of the ischemic condition, he added.

Referred to Stanford for consultation, the patient gave his informed consent for the experimental treatment. The laser successfully re-established arterial blood flow, Ginsburg reports, and the patient was discharged the next day on aspirin alone.

"At the time of follow-up the patient continues to do well, with only leg 'fatigue' after walking two to three blocks, and no nocturnal or rest pain."

He added that much more basic and clinical data are needed before the procedure can become generally available.

-more-

9-22-83

The clinical trials at Stanford, ongoing since March, come after several years of experiments with animals, human cadavers, and cooperative research in optical physics.

Ginsburg's co-investigators include Drs. Diana Guthaner, R. Scott Mitchell, and Norman Shumway.

Recently, Ginsburg noted, balloon angioplasty has gained wide acceptance as a treatment for vascular disease. The procedure uses a catheter with an inflatable balloon within to flatten or re-shape atherosclerotic plaque obstructing the vessel. The laser, by contrast, vaporizes the offending plaque.

Ginsburg hopes the laser will find its place as a complementary tool to already established techniques such as balloon angioplasty and coronary bypass surgery, in which the obstruction is skirted by grafting a peripheral vein from the aorta to the connecting vessel.

"Laser angioplasty is not meant as a replacement procedure," he said, "but if used in conjunction with others, the resulting back-up effect will hopefully raise the odds of success." This is why cardiovascular surgeons led by department chairman Norman Shumway are looking at potential applications of the laser in the operating room.

These and other heart specialists' concerns will be the focus of an international symposium at Stanford planned for this November on "Innovations in the Treatment of Cardiovascular Disease." The conference, geared towards the medical community, is meant to provide the latest information on new treatments and research areas, including lasers.

Ginsburg is program director of the symposium, which is being sponsored through an educational grant from Cooper Medical Corporation in Mountain View.

Already come into its own in fields like ophthalmology, gastroenterology, otolaryngology, dermatology, gynecology, neurosurgery, and even oncology, the laser's potential as a heart specialist's tool has only recently been explored by research teams using various approaches around the country.

"Laser energy has two primary uses in the cardiovascular system," explained Ginsburg. One use, he said, is for the removal of blood clots and atherosclerotic plaque obstructing coronary or peripheral vessels. The other use is to coagulate blood or arrest bleeding, for example to stop hemorrhage from leaking blood vessels.

Einstein first predicted in 1916 that electrons could be stimulated to emit photons of light energy of a certain wavelength. The acronym "laser" stands for "light amplification by stimulated emission of radiation."

Electrical energy is sent through a tube of conducting material. The atoms of the laser medium are excited, and as they return to their normal state, monochromatic, in-phase light waves are emitted in a focused beam. This is where the laser derives its tremendous energy.

What kind of laserwhat energy level, wavelength, and conducting substanceto use is determined by the needs of the application in question.

The powerful argon laser, because of the substance's ready absorption by red pigment such as hemoglobin, its easy transmission through tiny glass fibers, and its commercial availability, became the cardiologists' laser of choice.

-more-

Vascular work by laser, Ginsburg said, requires the use of fibers to serve as a delivery system. Sneaking the fibers through a catheter to the point of obstruction, the Stanford physicians use X-ray visualization for monitoring their work. This they consider preferable to developing and utilizing new technologies as some research teams have done.

The procedure, requiring only overnight hospitalization, can be accomplished in the catheterization laboratory.

Among the advantages of the laser envisioned by medical scientists are the ability to control precisely the amount and direction of energy utilized in a procedure, to avoid invasive surgery, and to reach fairly inaccessible recesses of the human body. It is relatively simple to learn to use, and the laser beam generates heat which prevents infection at the site of contact.

Once they'd chosen their laser and delivery system, however, Ginsburg's team still faced the question of safety. Risks to the patient are small but real, he said. There are the general risks of angiography itself, but also the possibility of perforation of the blood vessel wall.

In their clinical trials so far the Stanford physicians have used a balloon guiding catheter as a precaution against inadvertent perforation. "In case of perforation," Ginsburg explained, "the catheter could have been advanced to the site of injury and inflated to prevent hemorrhage."

Other routine precautions are taken whenever lasers are used, to protect the operator as well as the patient.

There are still other problems to be resolved, Ginsburg said. Absolutely accurate direction of the laser beam hasn't been attained, the present system presents very low energy efficiency, and much is still unknown about the long-term effects of laser radiation on the vessel wall and atherosclerotic lesions. Moreover, the ideal delivery system has yet to be developed, particularly for small or tortuous arterial vessels.

Once the problems have been dealt with, other potential applications of the laser in cardiology include correcting certain heart defects in infants as well as heart beat irregularities in adults, Ginsburg said.

STANFORD—

STANFORD SCIENTISTS DISCUSS CANCER RESEARCH

"The Genetics of Cancer," a look at potential underlying causes and cures of the killer malady, will feature lectures by three Stanford University Medical Center researchers.

The free public lecture, a community outreach forum to increase public awreness of cancer research, is scheduled at 8 p.m., Wednesday, Oct. 5 in the Sherman Fairchild Auditorium. The program is co-sponsored by Stanford and the American Cancer Society Santa Clara County Unit.

Speakers and their topics are Jeffrey L. Sklar, assistant professor of pathology, "Cancer Genes and Cancer Diagnosis"; Robert T. Schimke, professor of biology, "Cancer Cells' Response to Chemotherapy; and Irving L. Weissman, professor of pathology, "Cancer Genes Expressed at the Cell Surface."

In recent years, cancer research has focused increasingly on genetic engineering and how normal, healthy human genes change to become cancerous.

Sklar, who came to Stanford as a pathology intern in 1977 after receiving an M.D. and advanced training at Yale University, currently is studying the molecular genetics of malignant white blood cells and basic mechanisms of gene expression in mammalian cells.

In addition to a general introduction on the genetics of cancer, Sklar will be talking about a new diagnostic test for B-cell lymphoma.

Weissman, a Stanford Medical School graduate who became a full professor in 1981, has been studying immune cells of the bone marrow, particularly as they involve the mechanisms by which they are directed to other sites in the body. This potentially could offer insights into the causes and mechanisms of various blood cancers.

Schimke has been studying gene amplification, which includes the process by which increasing concentrations of anti-cancer drugs cause the targeted cells to become drug resistant. By determining thresholds of resistance, chemotherapy could become more effective. Schimke received both his undergraduate degree and M.D. from Stanford.

The three speakers are among 11 Stanford researchers receiving $655,575 in ACS funding this year.

Moderator for the forum is Richard A. Bohannon, a San Francisco physician who serves as chairman of the professional education committee of the California Division, American Cancer Society.

YOUNGSTERS REUNITE AFTER ROCKY START IN LIFE

Editors: Photos available upon request if not included.

STANFORD—

Once they were tiny, too small in an earlier era to survive.

But on Sunday, Sept. 11, about 200 playful youngsters munched cookies, giggled with Big Bird, Ronald McDonald and the Cookie Monster, and watched puppets—as several of their Stanford University Medical Center physicians were dumped good-naturedly into tanks of water.

The celebration was a reunion for former patients of Stanford's intensive care nursery, and one story after another illustrated that not only are premature and critically ill infants surviving in greater numbers than ever before, but many are growing to lead normal lives—albeit sometimes with minimal lingering handicaps.

Family members, often veterans themselves of scores of nervous hours in a waiting room, came to the hospital's garden patio too for the occasion. And some of the happiest partygoers were members of the health care team responsible, along with constantly advancing technologies, for the positive outcomes experienced by families in the past few years.

"We've always been concerned about how our babies do after leaving the nursery," said Dr. Philip Sunshine, professor of pediatrics and director of the ICN, addressing the crowd. "So this day is like a Godsend for us. We hope it will be an annual event."

"These babies have been through such hard times, and to see them come back with such spirit is great," said Barb Magee, an ICN nurse who helped arrange the affair, to which all ICN graduates since 1978 were invited. "First you recognize the parents; then the pieces begin to fall in place and you remember the baby," Magee explained as she watched assorted groups arriving.

Featured fun at the auxiliary-sponsored party included "Dunk the Doc," a jumping jack air pillow, clown visits, puppet shows, face painting, balloons and refreshments.

"I think I've had a guardian angel looking over me," exclaimed a single mother, Mary Ann Mitchell of Sunnyvale. Mitchell's baby Christy, now nine-and-a-half months old, was born nine weeks premature and spent seven weeks in the ICN. "But other than being very small, she really hasn't had any problems," said her mom.

9-13-83

-more-

Mitchell's hospital roommate, Jenny Paulsen of Cupertino, delivered baby Brittney one day after Christy was born. The two women had been given the same due date, they recall. "Our babies became roommates too."

Paulsen and her husband Brad said that Brittney, who was actually 11 weeks premature and also very small, suffered from apneas, or breathing difficulties, and some lung problems as well.

"It was especially hard for us," said Brad, "because it was around the holidays that all this was happening. Brittney was born the day before Thanksgiving. She spent a month in Stanford's ICN, and then a month at El Camino Hospital."

The Paulsens received emotional support from their family as well as the hospital staff. Charlene Canger, the ICN's social worker, said that a parent support network is now forming, to match up ICN graduate parents with families of babies presently in the nursery. The primary focus will be telephone support calls or visits.

Currently, the network is meeting once a month. Members also plan to use these or other sesions as supportive meetings for themselves to discuss issues of parenting *after* the ICN experience.

"The first year is especially difficult," Canger explained, "even in trying to get a babysitter to stay with your child, for example."

Jenny Paulsen added, "Sometimes it's *harder* when you take the baby home. I wasn't prepared for all the screaming 24 hours a day, for one thing. I was expecting Brittney to be like any other newborn when we brought her home, but she wasn't."

With Brittney progress is slow but sure, and her parents said she's fine now. "She is our first, and no, I don't want anymore," said her mother.

"Oh, I want ten more," Mitchell chimed in, just to illustrate the wide range of reactions to what always starts out a crisis situation. Mitchell's coming home though, she admitted, was less turbulent than the Paulsens'. The two women have become good friends.

What would they advise parents plunged, without warning, into the ICN experience? "You just have to take things a day at a time," Paulsen said, "and don't expect too much at the start."

Among those attending the reunion were a set of ICN graduate twins, a group of quadruplets, and a little boy born quite prematurely to two deaf parents.

At one point Dr. David Smith, a former fellow in the ICN now attending in pediatrics, showed another side to his talents by performing on the guitar, lyrics he'd composed about the ICN—this time from a baby's point of view.

VOLUNTEERS SOUGHT FOR WEIGHT LOSS STUDY

STANFORD—

Exercise or diet: which is the best route to weight loss?

The Stanford Heart Disease Prevention Program (SHDPP) is attempting to answer that question, and volunteers are being sought.

Specifically, the SHDPP is looking for moderately overweight and sedentary but otherwise healthy males, aged 30-59, living and-or working close to Stanford.

The men will be divided randomly into three groups. One group will participate in a one-year weight loss plan while remaining sedentary. The second group will join a one-year exercise program while continuing to eat about the same number of calories as before.

Members of a third group will change neither their diet nor their exercise habits and thus serve as a reference group for a year, after which they will be offered the best available weight loss program.

Besides weight loss, SHDPP personnel will take other medical and nutritional measurements (such as cholesterol and blood pressure) which may affect cardiac risk.

The diet and exercise groups will be compared to determine which lifestyle change might be more beneficial to overall health.

All participants will receive general nutritional counseling before being assigned to a group. After the first year, participants will receive followup exams during a second year to determine which of the two lifestyle changes is easier to adhere to.

For further information, call (415) 497-9646 between 11 a.m. and 2 p.m., Monday through Friday. Participants must fall within predetermined weight ranges. For example, 5-foot-10 men must weigh between 180 and 222 pounds with indoor clothes and without shoes.

Principal investigator for the project is Peter D. Wood, professor of medicine (research), and deputy director of SHDPP.

DIABETIC VOLUNTEERS NEEDED

STANFORD—

Do people with diabetes metabolize blood glucose inefficiently?

Diabetic volunteers are needed to help answer this question by participating in research conducted by Dr. Gerald Reaven and associates at the clinical research center at Stanford University Hospital.

To be eligible for this study, volunteers must have adult onset diabetes; be between 20 and 80 years of age, male or female; and be in good general health.

Participants will be offered the following free of charge: evaluation of blood sugar and insulin; routine health evaluation including liver and kidney function test, cardiogram, physical exam, and dietary evaluation.

Anyone interested or wishing further information should call Dr. Chris Donner or Dr. Clarie Hollenbeck, at (415) 497-6973 between 9 a.m. and noon; or Ann Coulston, R.D., at (415) 497-5430 between 1 and 5 p.m.

ARTHRITIS CLASSES: EXPANDING OBJECTIVES

Note: Photos available upon request if not included.

STANFORD—

The thumb-walk, the elbow chop and the heel-toe dance are just a few of the exercises taught in Stanford's arthritis self-help classes, a new series of which is scheduled to begin in October.

The classes, which have been cosponsored by Stanford and the Arthritis Foundation for the past four years, aim to drive home the fact that there are numerous things arthritis sufferers can do to help themselves.

And now, in addition to looking at the efficiency of patient education, researchers plan to expand the project to look at the psychological outcomes of teaching people to manage their own arthritic pain. "We'll conduct a two-year study to look at the effectiveness of long-term reinforcement as well," said research associate Dr. Kate Lorig.

The courses are open to anyone with arthritis. They provide information about arthritis, how best to use arthritis medication, how to design an appropriate exercise program, how to deal with emotional and physical problems created by the condition, and how to work more closely with one's physician.

Participants practice exercises and relaxation techniques and discuss nutritional concerns. They complete questionnaires at several intervals during the course and are continually compared to a control group of future participants.

The fall series will last six weeks. Each class is taught by two community leaders who have been trained by Lorig. Many leaders have arthritis themselves or in their families, some are retired health care professionals, and others are simply people interested in helping others.

Morning, afternoon and evening sessions will be held at 14 locations in the Bay Area including Palo Alto, Cupertino, Sunnyvale, Santa Clara, San Jose, Redwood City, San Mateo, San Francisco and South San Francisco. Classes meet for two hours weekly.

Pre-registration is necessary and enrollment is limited. A small fee will be charged, and scholarships are available. For information or applications to the arthritis self-management course, call (415) 497-7935.

STANFORD—

Stanford University Medical Center's Office of Communications, which includes the News Bureau, has a new location effective today, Sept.2.

The new office is at 750 Welch Rd., Suite 301, Palo Alto, Calif. 94304. The phone number remains 497-6911.

The move was necessitated by the consolidation of the Medical Center's Public Events Office with the Office of Communications, and the Department of Medicine's need for more academic space. The Office of Communications is adopting a typesetting computer system that will interface with the University's News and Publications Service, allowing a more efficient service, said Communications Director Spyros Andreopoulos.

The Communications Office prepares the *Medical Center Memo* section of the *Campus Report*, sends out news releases about the Medical Center to media, and provides a number of other communications services. It also publishes *Stanford Medicine*, the new Medical Center-wide magazine scheduled to debut this fall.

The magazine, to be of higher quality and more consumer-oriented than previous publications, will be distributed to faculty, staff, patients, referring physicians, donors, foundations and medical alumni, among others. It replaces *The Healing Arts* and *Stanford M.D.*.

PROMINENT SPEAKER TO HIGHLIGHT SOCIAL WORK CELEBRATION

STANFORD—

The 70th anniversary celebration banquet for the Department of Clinical Social Work at Stanford University Hospital will feature Virginia Satir, internationally renowned therapist and author, speaking on "Families in the '80s."

The banquet will be held Thursday, Sept. 15, at the Faculty Club on campus. No host cocktails will begin 5:30 p.m., with dinner served at 6:30. A fee will be charged.

Satir, who has shared her work all over the world, is frequently thought of as *the* innovator of the approach that brings the entire family into the therapist's office. Considered unorthodox 30 years ago, her approach has now been widely adopted.

Satir applies her beliefs to business, institutional practices, and other human systems.

She was one of the founders of California's Mental Research Institute. In 1976, she created the AVANTA Network, of people who have studied with her and who present workshops around the world. She was a director at the Esalen Institute in California.

The awards and recognition banquet is the culmination of a year-long celebration as social services at Stanford attains its 70th year of evolution, involving issues which keep changing as rapidly as science pushes the state of medical technology forward.

Stanford's was one of the first departments of clinical social work to be established in a hospital in this country, said Wilbur Wright, director. "It was certainly the first on the west coast, started about two years after the first one began at Massachusetts General Hospital in Boston."

The Hospital Auxiliary was responsible for the department's funding support through 1940, Wright said.

The banquet will also include an awards ceremony and a presentation of the department history to both the University and Hospital archives.

Those wishing to attend should respond by Sept. 6 to (415) 497-5615. Further information can also be obtained at this number.

(Members of the news media should make arrangements with the News Bureau at 497-6911.)

RESEARCHER SAYS PHYSICIANS SHOULD HEED HEART STUDY

STANFORD—

Results of a decade-long federally sponsored heart disease study conducted partly at Stanford Medical Center will have impact only if practicing physicians carefully heed the findings, says the cardiologist who directed Stanford's component of the research.

Results of the Coronary Artery Surgery Study (CASS) were released by the National Heart, Lung and Blood Institute Wednesday in Washington.

Edwin Alderman, associate professor of medicine (cardiology) at Stanford, said the research shows "there is no difference in lifespan for those heart patients who suffer from minimal or absent symptoms. He said this group represents about 15 percent of potential coronary surgery candidates, and emphasized that the remaining 85 percent of candidiates clearly need surgery for relief of symptoms.

"Many of the 15 percent of patients who don't need surgery now, Alderman said in an interview Thursday after returning to Stanford, "will eventually need surgery as their symptoms worsen.

"However, what is important to the patient and the physician is that there appears to be no benefit for a select group of patients to undergo surgery before symptoms appear.

"Some physicians have recommended surgery for patients with absent or mild symptoms heart conditions on the theory that it would help prevent a major heart attack or death. What this study shows decisively is that medical therapy alone produces the same results" for these patients.

Alderman said he is hopeful that physicians will pay close attention to the study and perhaps be even more cautious than before in recommending surgery for the 15 percent of asymptomatic patients.

"The theory that preventive (prophylactic) surgery will usually reduce mortality appears not to be valid," Alderman said. "However, the study did snow that even mild symptoms were substantially helped by surgery."

-more-

10-27-83

2-2-2

The study followed 780 patients at 11 institutions with mild ischemic heart disease. Fifty of the patients were at Stanford.

At the Washington news conference, Dr. Thomas Killip, chairman of the department of medicine at Henry Ford Hospital in Detroit and chairman of the CASS steering committee, said "there is no significant difference in survival between medically or surgically assigned patients overall. At six years, 90 percent of the medically assigned and 92 percent of the surgically assigned patients are alive."

Killip added that the surgical patients enjoyed greater relief from angina (heart pain) and were able to exercise longer and take fewer drugs.

"Surgery can provide a better life for patients with coronary artery disease," Alderman said. "But what we see more clearly from this study, is that physicians can recommend that surgery be deferred for many patients until symptoms appear."

Alderman cautioned that certain patients, specifically those with obstructions in the left main coronary artery or those who have previously had a heart attack, may continue to require surgery whether or not they have symptoms.

The CASS study disclosed that more than 1 million persons have undergone coronary artery bypass surgery since it was introduced in 1968.

ANDERS DELIVERS CHILD PSYCHIATRY LECTURE

STANFORD—

Dr. Thomas F. Anders, professor of psychiatry and director of the division of child psychiatry and child development, will speak to the general public on "Body Clocks and Body Rhythms in Child Psychiatry" at 8 p.m., Thursday, Nov. 3 in Fairchild Auditorium of Stanford University Medical School.

Anders said the talk will focus on some of the latest theories, techniques and research in child psychiatry, including how physical time cycles influence behavior of young people. Dr. Thomas A. Gonda, chairman of the department of psychiatry and behavioral sciences, will serve as moderator.

No reservations are needed for the free lecture, which is sponsored by the Friends of Psychiatry and Behavioral Sciences, a non-profit group comprised primarily of community volunteers who are interested in promoting education in behaviorial sciences and supporting psychiatric activities at Stanford.

For further information, call (415) 497-6376.

BLOOD PRESSURE, DRUG STUDIES STILL SEEK VOLUNTEERS

STANFORD—

Volunteers between the ages of 20 and 70 are still needed to participate in studies to confirm the effectiveness of various anti-hypertensive medications.

The studies, which compare test preparations with placebos as well as medications already on the market, are based at the Veterans Administration Medical Center in Palo Alto; principal investigator is Dr. Peter Rudd, assistant professor of medicine at Stanford.

Volunteers are needed who have mild to moderate high blood pressure. Participants are offered free comprehensive medical evaluations at the beginning and end of the studies. This also includes screening and lab tests. Travel reimbursement is offered, and scheduling may be worked around participants' job responsibilities.

Anyone interested should call Valerie Vierra, R.N., at (415) 497-5000, ext. 5918, weekdays from 10 a.m. to 2 p.m.

* * * * * *

Healthy, Caucasian, non-smoking females, aged 60 to 80 and currently taking Premarin or estrogen, are still needed to participate in an ongoing drug study at Stanford.

The study, which examines age-related changes in liver clearance of drugs metabolized by different pathways, currently seeks subjects for the weeks of Nov. 14 and 28. Volunteers will receive compensation.

Participants spend one week in the clinical research center at Stanford. Three relatively non-toxic drugs are administered. (Side effects, if any, are minimal, said research nurse Marni Brown.) Blood and urine samples are taken.

Principal investigator is Dr. Terrence Blaschke, chief of clinical pharmacology. Anyone interested should call Marni Brown at (415) 497-5266.

FOR IMMEDIATE RELEASE

EDITORS: This story is based on the lead article of the fall issue of *Stanford Medicine*, a new magazine published by the Stanford University Medical Center. Copies are available on request if not included with story.

HEART TRANSPLANTS REWRITING THE BOOK ON HEART DISEASE

STANFORD—

Spinoffs from heart transplant surgery are turning out to be as important as the operation itself, says Dr. Donald C. Harrison, Stanford's chief of cardiology.

"Every major clinical advance—even if you don't know how it works—eventually forces people to return to basics, to understand the science," he says.

The spinoffs were made possible, in part, by the availability of fresh tissue from the discarded hearts of patients who had transplants, explains Dr. Edward Stinson, the cardiovascular surgery professor who directs Stanford's heart transplantation program.

The study of this tissue, as well as clinical observations on patients, have produced important new knowledge about coronary artery disease, the chemical pathways in the heart, and the effects of heart drugs, Stinson adds. This couldn't have been learned from animal studies alone.

A dramatic example is the development of the heart biopsy technique made possible by the perfection of a Japanese invention, the bioptome. This instrument—essentially a piece of wire with a clipper at the end—is inserted into the patient's jugular vein and threaded down into the heart, where it snips a small sample of heart tissue.

By permitting direct tissue study of graft rejection early, this instrument has extended patient survivals, according to pathologist Dr. Margaret Billingham. But it has also permitted physicians to diagnose and treat heart disease in a broader context and is changing cardiology practice all over the world.

Doctors, for instance, had no information about why a patient had cardiomyopathy, a chronic heart muscle disease that involves permanent damage to the heart. They only knew what heart tissue looked like after the patient had died and an autopsy was performed. "Now we are learning if the disease is potentially reversible," Billingham says.

Billingham, Harrison and Stinson are among several Stanford faculty members interviewed by the editors of *Stanford Medicine*, the magazine of the Stanford University Medical Center. The editors wanted to know what had been learned from the 15-year-old heart transplantation program besides its obvious benefits to carefully selected patients.

10-20-83 -more-

"It has put Stanford in a unique position to pursue research," the magazine quotes Dr. Thomas C. Merigan, chief of infectious diseases, as saying. The collaborative studies spawned by heart transplants have involved experts in cardiology, lung physiology, virology, hematology, and cancer research.

Merigan, for example, is applying his experience developed from treating infections in heart transplant patients to patients with acquired immunodeficiency syndrome (AIDS).

"Both types of patients," he explains, "tend to develop cytomegalovirus infections, which lead to complications with infectious microorganisms. One problem is a disease, *pneumocystis carinii*, a leading cause of death in AIDS victims. The same infection affected many of the early heart transplant patients until better antirejection drugs lessened the intensity of this complication."

Merigan speculates there is more than one factor in AIDS patients interacting to produce "opportunistic" infections. "Our experience in dealing with these problems may help unravel this mystery," he adds.

The magazine lists several scientific spinoffs made possible by Stanford's heart transplant experience. They are:

* better understanding of accelerated atherosclerosis in heart transplant recipients and methods for its prevention.

* improvements in early diagnosis of graft rejection through the validation of the accuracy of space-age tools. These include echocardiography (sonar techniques), phonocardiography (recordings of heart sounds), and EKG recordings from the inner surface of the heart.

* development of more effective antirejection drugs.

* better scientific understanding of the mechanisms that trigger coronary artery spasm, a source of pain and often a cause of injury to the heart.

* the finding that severely failing human hearts have a common biochemical abnormality—a marked reduction in beta drug receptors. These are molecules on the surface of heart cells that mediate heart response to adrenaline-like compounds. Loss of beta-receptors means hormones can no longer stimulate the heart, leading to the patient's demise.

* improvements in tissue matching techniques.

The most important spinoff of heart transplantation, the article concludes, has been the revival of Dr. Norman Shumway's lifelong dream. The pioneer of heart transplants had long believed that for some patients replacing only the heart was not sufficient. Their lungs are often damaged due to high blood pressure. Patients with damaged lungs, from either a failing heart or diseased lungs, are a poor risk for just a heart transplant. The only recourse is to replace both.

After extensive tests on a new antirejection drug, cyclosporine, in monkeys, the moment arrived.

To date, 15 patients have received combined heart-lung transplants with 10 patients now living.

Some of these people had never been able to do anything physically demanding in their lives. Now they run, swim, play football or ride bikes, says Dr. Stuart Jamieson who directs the heart-lung transplant program.

NATIONWIDE STUDY TO CHART DEVELOPMENT OF PREMATURE INFANTS

STANFORD—

A Stanford professor of pediatrics has been named to direct an $11 million nationwide study of the ways health and educational supplements can boost premature infants in their first years of life.

The Robert Wood Johnson Foundation of Princeton, New Jersey recently named Dr. Ruth T. Gross to lead its "Infant Health and Development Program," a study which will chronicle the development of more than 500 children at six U.S. medical centers over the next four years.

Two decades of advances in technology and in the understanding of the special needs of infants born seven or eight weeks early, have greatly increased the infant survival rate, Gross said. Three pound newborns are fairly common in today's intensive care nurseries, and even two pound babies often thrive.

But a growing number of follow-up studies on recent graduates of these nurseries have shown that very low birthweight infants are four times more likely than larger newborns to require rehospitalization in their first year. Other studies have hinted that the 240,000 U.S. children who are born prematurely each year are more likely to show delayed language development, disabling behavioral problems, and lower academic achievement than children of normal birth weight.

Programs that provide supplemental health care, and social and educational support to these children and their families seem to boost the children in their later preschool development, said Gross but, until now, no one has defined the scope of the problem or identified which parts of these supplemental programs are most useful.

The goal of the current study, she said, is to see which treatments are most effective for these babies, and which problems can be prevented.

Each child in the upcoming study will be randomly assigned into one of two groups, she said. Both groups will receive ongoing medical care. In addition, infants in one of the groups will be involved in a supplementary educational program, first in the home and later in preschool classes. Much of the program will focus on parents and the family, said Gross, teaching those closest to the infant to respond to the child's special needs.

The six sites slated to conduct the collaborative study will be announced in June of next year, she said. In addition to Gross, Stanford faculty members Helena C. Kraemer, associate professor of biostatistics in the department of psychiatry and behavioral sciences, and Lee Cronbach, professor emeritus of education, will collaborate in coordinating the study. Donna K. Spiker will serve as deputy director of the project.

2-2-2

Widespread medicinal leeching produced a scientific bonus as leading scientists of the day delved into the behavior and anatomy of a creature that might otherwise have been overlooked. As a result, the 400 or so neurons that make up the creature's brain and nervous system have become as familiar and recognizable to today's neuroscientists as a hometown roadmap.

Each movement, hesitation, mating, feeding and sensation can be traced to an interaction of electrical signals that pulse along the relatively simple nerve network. Nicholls is particularly interested in communication between cells.

"We're interested in the question of how nerve cells become connected to each other," he said, "because they have to connect correctly. You can't make a television set by jumbling up a whole lot of components and hope they'll connect up right. Everything has to go to the right place, and there's very little existing information about how cells make these choices."

Teasing apart the physiological and biochemical influences that determine these "correct connections" is difficult in an intact animal, but Nicholls and his team capitalize on a valuable characteristic of leech nerve cells—their ability to regenerate—to solve the problem.

Unlike cells in a human central nervous system, which won't reconnect once severed, damaged leech cells "reconnect with tremendous accuracy," Nicholls said.

"This enables us to simplify the system," he said. We take cells out of the brain of the leech and put them in a dish in culture." Nicholls and his colleagues Pierre Drapeau and Robin Davis found that, instead of randomly sprouting connective cables to any nearby cell, the isolated neurons in an experimental dish "recognized" and sought specific connections with the same type of cell they had been connected to in the leech body.

The groundwork is now laid for a finely tuned understanding of the chemical and structural cues that regenerating neurons use to zero in on their proper targets, Nicholls said, a first step toward understanding similar cellular communication in higher animals.

"We wrote the book," the scientist said, " to try to communicate the intellectual excitement of trying to solve the circuitry and logic of a finite, well-organized nervous system one cell at a time."

PHYSICIANS FEAR NEW MEDICARE PAYMENT PLAN MAY ADVERSELY AFFECT HEALTH CARE

STANFORD—

Medicare's new method of paying hospitals has administrators worried that they will be forced to cut back on patient services, and physicians fearful that they will have to change the way they treat their patients.

The stated intent of the prospective payment system (PPS), which Congress approved last April, is to cap spiraling health care costs. It involves all hospitals except those specializing in children's, long-term, rehabilitation, and psychiatric care. The problem is the public may not realize or like the way it will affect the care they receive, said Dr. James Silverman, chief of staff at Stanford University Hospital.

"The goal of the PPS is to take money out of the hospital industry. With less money, fewer services can be offered to patients. Yet patient expectations will remain the same," he explained.

"The new payment method will have the greatest impact on the health care industry since Medicare was implemented in the 1960s," Silverman added.

"Everyone favors cutting health care costs, but few would favor less medical care for themselves or members of their family," said Joyce Miller, associate director of nursing. "Health professionals are saying that with the new payment method, they can't do everthing for everyone. There's going to be some rationing of health care. It's the start of a two-tier health system."

"A nail is being pounded into the health care coffin," said David Sakai, director of finance.

The new payment plan is based on a diagnosis related groups (DRGs) classification system. In brief, the federal government will pay hospitals a set rate for patient services. That rate is determined by the DRG: "a scheme that categorizes patients who are medically related in terms of diagnoses and treatment, and statistically similar in lengths of stay," according to Marion O'Brien, director of medical records.

If the amount paid by Medicare is greater than the hospital's cost of the services, the hospital may profit. If the amount is less than the cost, the hospital must absorb the loss.

It wouldn't be so bad, Silverman explained, if this type of payment plan only involved those covered by Medicare, who account for about 25 percent of Stanford's patients. But the PPS follows on the heels of a similar state program for the elderly and poor, which covers about 13 percent of Stanford's patients. And other insurance carriers will be quick to follow, he predicted.

Thus, the incentive is there for physicians to examine the way they practice, Miller said. They'll have to consider if everything they order, such as tests or supplemental services, is absolutely essential for their patients' care.

Admittedly one of a small minority, Dr. Kenneth Melmon, chairman of the department of medicine, said he thinks the new plan may be of some benefit. "We'll be able to provide the same quality of care at lower cost."

-more-

10-17-83

Most physicians, already leery of cutting corners because of the constant threat of malpractice suits, are alarmed that the public may interpret the decrease in quantity of procedures and services as a decrease in quality of care, Silverman said.

From its inception, Medicare, which primarily covers health care for the elderly, has paid hospitals for patient services on a daily rate basis. Ancillary services, those provided by non-physician personnel such as dietitians, were paid separately.

PPS has changed all of that. Like an outline, the system has major diagnostic categories based on the body's organ systems. Each has subcategories, for a grand total of 468 different diagnostic classifications. They are based on an international classification of diseases listing that converts any diagnosis into numerical terms, thus making them universally understandable.

After a patient is discharged, specially trained personnel in the medical records department process the necessary forms for payment. They assign a DRG based on the chart information that was recorded by the physician during the patient's hospital stay.

Key to survival under PPS, O'Brien said, is complete and accurate information from the physician. For instance, the DRG—and the amount of payment—differs if a physician writes that a patient has alcoholism with cirrhosis, or cirrhosis with alcoholism. If this sounds complex, it's only the beginning.

Consider, for example, a car accident victim brought to the emergency room with a broken hip, a concussion, and a damaged liver. Each could be considered the principle diagnosis, defined as the reason the patient has to be admitted to the hospital. Each also falls under a different DRG, with varying amounts of payment.

Regardless of the total charges accumulated in treating all the injuries, the hospital can only bill Medicare for one DRG. The payment is in full, and non-negotiable. The patient cannot be billed to help make up the difference.

No problem, one may think. The hospital could simply admit the patient again for treatment for each injury. Medicare's think tank has already accounted for that possibility. Private review organizations (PROs), contracted by the federal government on a one-per-state basis, will monitor hospitals' activities. They'll watch for adverse admission and discharge, and coding patterns in each hospital, and will compare patterns between hospitals to make sure no institution is "taking advantage" of the system, O'Brien explained.

"The PROs will be like big brother watching," she said.

PROs succeed professional standard review organizations, which lost federal funding in 1982. Their function, which PROs will take on, was to serve as an internal method of monitoring quality of care and cost containment for Medicare patients.

Not every hospital will receive the same rate of pay. The plan is scheduled to be phased in over a three year period, beginning with each hospital's fiscal year after Oct. 1, 1983. Stanford's fiscal year starts Sept. 1, for example. The new payment method, then, will not begin until Sept. 1, 1984.

During the first phasing-in year, hospitals' payment rates will consist of 25 percent the DRG rate, and 75 percent the rate at which they've billed Medicare in the past. The second year, this will go to a 50/50 split; by the fourth year, Medicare payments to hospitals will be based completely on DRG rates.

Medicare's think tank acknowledged that service costs vary throughout the country, based on local economies, salaries, and other factors. For now, the government has established nine geographical regions, each with a different rate. For example, nursing salaries in the East are significantly lower than in the West, thereby lowering the total cost of health care. The government also established a national rate, based on the average of these nine regional rates. Initially, the DRG rate will be comprised of 25 percent the national rate, and 75 percent the regional rate. Eventually this difference will also be eliminated, and one national rate will prevail As such, hospitals in regions with lower costs will ultimately be relatively better off than those in regions with higher costs, O'Brien observed.

The PPS also takes into account extra costs incurred by teaching hospitals such as Stanford, at least for now, Silverman said. Because training tomorrow's physicians is costly in terms of demonstrating and comparing diagnostic tests and medical procedures, teaching hospitals' payments are greater than hospitals without the responsibility.

"I don't know how long this allowance will last, but my sense is that we shouldn't count on it," Silverman said. "There's the opinion that the government will always look out for institutions like Stanford. My experience is that it doesn't treat teaching hospitals any different at all."

However, Finance Director Sakai feels differently. "As long as society believes there is a need for physicians, the allowance will continue."

This brings up another issue that has many teaching physicians worried. Under the PPS, will money exist to buy new equipment, or to develop new procedures? For example, consider Stanford's tissue typing laboratory, explained Dr. David Korn, pathology department chairman. "By itself, it operates at a loss. Yet, it has been instrumental in the success of organ transplant procedures, such as heart transplants, that have advanced medicine.

"Under the PPS, the laboratory would probably be eliminated. This type of attitude is more exaggerated in a teaching hospital, where the mission is the pursuit of new knowledge."

"The PPS could, if this type of thinking results, have a stagnating effect on medicine," Korn concluded.

"The new system discourages new technology and procedures unless they will be able to perform less expensively," Sakai confirmed.

Not only will it affect advances in medicine, O'Brien said, it will affect the freedom with which physicians make decisions about patient care. "The PPS doesn't allow for any individuality or innovation," she said "If five different physicians are using five different types of pacemakers for their patients, it may be decided for them on a cost-containment basis which one would be the overall best. Physicians are not going to be afforded the luxury of choosing their techniques as much as in the past."

Another aspect the PPS does not accomodate for is the severity of sickness of a hospital's patients. National studies have shown that Stanford's patients, for example, are sicker than all but four other institutions' patients. This implies that it takes more time, more care, and consequently more money, to treat these patients Medicare's plan includes a concept called outliers that is supposed to address this type of situation.

One factor determining DRG rates is the patient's length of stay in the hospital for a specific diagnosis. Medicare, O'Brien explained, will pay extra if a patient is hospitalized longer than the DRG specifies. However, there is a lapse between the length of stay the DRG allows—and includes in its payment rate—and the point at which outlier payments start. Once they do begin, they pay only 60 percent of the total extra cost. The hospital must absorb the difference.

"Any attempt to lump individual diverse patients under one heading is dangerous," warned Korn. "One patient may be relatively all right, while another may be much sicker. To imply by DRG classification that they require the same amount of treatment just won't work."

In addition to the extra data collection and medical record processing required by Medicare's new payment plan, an extensive education process must take place, Silverman said. Stanford's nursing service is sponsoring a symposium, "Health Care Financing: Effect of Prospective Reimbursement on Patient Services," on Oct. 20-21. Stanford administrators and physicians are attending formal sessions at the hospital to learn about the system. Even more, Silverman explained, physicians, and hospital administrators will have to change their way of thinking in order to survive.

"The hospital industry is like the airline industry," he continued. "The airlines started offering discount seats reasoning that it was better to get some money rather than let the seat stay empty and get no money at all. When they started discounting all their seats, however, they found they couldn't survive.

"Hospitals can absorb the loss if some patients pay less than the cost of their treatment. Hospitals cannot operate if the policy expands to all patients," Silverman concluded.

EXPERT EXPLAINS WHY HOSPITAL COST CONTAINMENT WORKS IN CANADA

STANFORD—

Regulatory strategies to contain rising hospital costs can work effectively, a Canadian study shows, even though it is unclear how they affect the quality of care.

The study compared the effectiveness of regulation in the Canadian province of Ontario with similar U.S. experience from 1968 to 1981. It showed that expenditures in Ontario increased by only 16 percent compared with an increase of 101 percent in the United States.

"We conclude that regulation can contain the growth of expenditures in the hospital sector even in the face of an incentive structure that does not promote cost consciousness on the part of patients and physicians," said Dr. Allan Detsky of the department of health administration at the University of Toronto.

Detsky spoke Monday (Oct.10) at a seminar sponsored by the Health Services Research Consortium at Stanford University School of Medicine. The study on which his talk was based was recently published in the New England Journal of Medicine.

"Data from U.S. studies," Detsky said, "have shown that 75 percent of all increases over and above inflation in the hospital sector could be accounted for by increases in the quality of care as measured by what economists term 'real inputs' employed per patient day."

These, he explained, involve physical things—more R.N.s, more hospital employees, supplies and sophisticated equipment.

Similar increases in the number of professional and other hospital employees occurred in Toronto's hospitals until 1968 when budgets were negotiated between individual hospital administrators and the Ontario Ministry of Health on a nonformula basis

Canada has had government-financed insurance for hospital services since 1961. The insurance plans are administered separately by each province, with costs shared by the federal and provincial governments

After Ontario introduced measures to control hospital costs in 1969, Detsky said, "real inputs per patient day grew at an average annual rate of 0.68 percent compared with 5.19 percent in the United States for the period from 1968 to 1980."

10/12/33 -more-

In Ontario only 13.9 percent of these increases beyond general inflation were accounted for by real inputs—labor costs, supplies and equipment, he said. This contrasts sharply with the U.S experience where 81 percent of the increases in costs per patient day were directly attributable to an increase in the quality of care and the price (wages) to pay for it.

"Ontario hospitals had been locked into an incentive structure that mimics the worst features of the U.S. system—that is a complete separation of physicians and patients from hospital costs," Detsky said. "However, the regulatory mechanism in Ontario has cornered hospitals in three ways.

This includes use of global budgets increased annually according to a formula, closing of unnecessary hospital beds, and limiting the number of labor hours.

Since 1969, Detsky said, similar regulatory strategies have been tried in the U.S. to curb rising hospital costs. These included the Economic Stabilization Program (wage and price controls) employed during the Nixon years and the voluntary cost-containment efforts encouraged by the Carter administration. In addition, prospective reimbursement experiments for hospitals have been tried by some states succesfully.

But these have led to a rash of law suits, appeals and court actions. "In terms of political turmoil, the costs have been high," Detsky said, "leading some to suggest that in the U.S. a painless regulatory system that effectively controls cost is certainly out of reach."

With few exceptions, in Ontario these consequences have been politically acceptable thus far, Detsky said.

RESEARCHERS STUDY WATER BEDS FOR PREEMIES

STANFORD—

Should premature infants sleep on continuously rocking water beds or on ones that move only at intervals? Does it matter if the motions are in any particular rhythm?

Questions like these still need answers, according to a Stanford researcher, especially as more hospital nurseries use water beds.

Dr. Anneliese F. Korner, professor of Psychiatry and Behavioral Sciences (research) at Stanford, and her colleagues are conducting a major three-year study to compare the effects of plain water beds, water beds with continuous oscillations, and others that move intermittently. The study is funded by the National Institute of Mental Health.

Korner's research during the last ten years has shown that gently moving water beds can significantly reduce apnea, or periodic stops in breathing, and bradycardia, slowing of the heart rate.

These findings are probably limited to apneic premature infants who are otherwise fairly healthy. The water beds do not seem to reduce apneic spells in highly unstable infants or in babies who are receiving drugs to reduce their apnea, Korner said.

Still to be determined is whether water bed use can improve the behavioral development of premature infants.

A pilot sudy conducted by Korner and her colleagues suggested that premature infants who were on water beds for long periods of time showed more mature spontaneous motor patterns, were more alert and less irritable than infants in the control group.

The water beds used in Korner's studies are programmed to move in the pattern of maternal biological rhythms which the infants would have been exposed to it they had not been born prematurely. She and other investigators believe that lack of exposure to such rhythms may be one of the factors responsible for the disorganized sleep and movements frequently seen in premature babies.

The continuous water bed movements are based on the maternal respiration rhythm—about 12 to 13 oscillations per minute. The intermittent oscillations are based on the basic rest-activity cycle. According to sleep researchers, adults experience a cycle of alternative quiet and activity about every 90 minutes throughout the day and night.

"Judging from the use of 'bump beds' which are air mattresses providing sudden jerks, and other types of water beds, it has been widely assumed that it is the oscillations that reduce the apnea," said Korner. That assumption, though, is not proved, she said.

"It is still unclear whether it is the oscillations, the maternal rhythms or the water bed itself that produces these effects," she said.

Two recent studies by Korner showed that babies had longer periods of quiet sleep and were less irritable and restless on waterbeds that moved either continuously or at intervals.

BRAIN WAVES OF PREMATURE INFANTS SERVE AS WINDOW ON LATER DEVELOPMENT

STANFORD—

The brain waves of a premature infant in the first weeks of life may be a sensitive indicator of the child's later neurological health, a Stanford researcher reports.

In addition to its predictive value, the electroencephalogram or "EEG" can give physicians a vivid view of ongoing activity in the tiny brain, said Dr. Barry Tharp, associate professor of neurology.

Although the EEG has been used for over 40 years as a tool to chart the activity of the adult brain, Tharp is one of the first to recognize its diagnostic value in infants born too soon.

In a study soon to be published in the medical journal *Neurology*, Tharp and his research associate, Robert R. Clancy, identified 44 infants who had been born seven or eight weeks prematurely and had suffered a brain hemorrhage. Noting that some of the children were normal at age two, while others showed signs of cerebral palsy, Tharp scoured the children's neurological records in search of early hints that could have helped doctors predict such differences in the children's development.

Among the myriad tests performed on the infants during their first weeks of life, only the EEG proved to be "a great predictor of outcome," said Tharp.

"Nine of twelve infants who had all normal or mildly abnormal EEGs had favorable outcomes," the scientists reported. "The nine infants whose worst EEGs were moderately abnormal experienced mixed outcomes ranging from normal survivors to death. All 23 infants with one or more markedly abnormal EEGs suffered unfavorable outcomes." Twenty of these died, and the other three suffered brain damage.

Usually, EEGs are performed only on patients suspected of having a neurological problem, and are not a part of the intensive care nursery's routine monitoring, he said. All the children in his study underwent the test because they suffered from postnatal bleeding in the brain, a malady that strikes about half of the smallest premature infants.

The hemorrhage, which can be caused by a sudden fluctuation in blood pressure, a lack of oxygen, or any of a variety of stresses on delicate blood vessels, may or may not cause permanent brain damage.

The electrical signals produced by brain tissue damaged by a hemorrhage or other insult are different from those produced by healthy tissue, Tharp found.

The next step was to gather as much information as possible about the brain waves of "healthy" premature infants, by monitoring many children at regular intervals in the first months after birth.

Tharp has completed such a study of 70 premature infants, and has just begun to analyze the data.

"In this study we have a big population ranging from really good looking infants who you would never know had anything wrong, to kids in deep coma and children who die," said Tharp.

Up until now, normal brain function in these infants has not been well studied, he said. "The whole field of neonatal neurology is fairly new," he said, "mainly because, until fairly recently, most of the really small preemies (those who weighed less than two pounds) didn't live. Now about 60 percent of the tiny ones survive.

" As more medical centers are getting into this field, and more and more neurologists are being asked to assess these children, the more important it is that they know what it is they're looking at," said Tharp, adding that eventually, round the clock EEG monitoring might be included in neonatal intensive care units.

"Currently, when a baby is born and transferred to the neonatal ICU, nearly everything is monitored—breathing, oxygen in the blood, pulse, blood pressure and kidney function, but not brain function." This is surprising, Tharp said, because "really, the bottom line you want to know is, is the brain okay?"

The main obstacles to continuous monitoring are technical, Tharp said, such as developing adequate equipment to store the large volumes of data recorded; and more importantly, knowing how to analyze this data once you have obtained it.

"Only as we have gained a better understanding of what constitutes normal and abnormal has monitoring become feasible," he said. For example, physicians know that a sudden drop in blood pressure alters the preemie EEG, but no one is certain how long-lasting the change is, and whether it indicates permanent or transient brain dysfunction, he said.

"How low can the oxygen content of a child's blood get before we should start worrying?" Tharp asked. "If the blood pressure is below a certain level for 25 minutes, does that affect the EEG? All these are things that we don't know yet, because no one has monitored kids in that way."

Tharp is especially interested in seizures—the scrambled bursts of electrical activity that occur more commonly in brain injured infants, or in those with a metabolic disorder than in healthy babies.

"It's probably only a problem when they occur in a repetitive fashion," he said. "Many people with epilepsy live perfectly normal lives with no damage resulting from their seizures. But we wonder, in young infants whose brains are very vulnerable to any kind of stress, whether perhaps the fact that these kids are having literally hundreds of seizures over three or four days might be doing permanent damage."

One goal of continuous EEG monitoring of babies at risk, Tharp said, is to amass a bank of data such as these, that will enable doctors "to predict seizures so that in the future we can treat kids prophylactically."

FUND RAISING AT MED CENTER HITS RECORD HIGH

STANFORD—

Fundraising results for the Stanford University Medical Center have reached a new high of $25.9 million in fiscal 1982-83, the Office of Medical Development reports.

The total money raised has exceeded the previous year by $6.2 million or 31.3 percent.

"This is an exceedingly fine record," said Dr. Lawrence G. Crowley, vice president for medical affairs. "It speaks well to the attractiveness of our programs, the quality of our faculty and the dedication and professionalism of our able medical development staff.

The fundraising results, Crowley commented, "bode well for the future and particularly for our very ambitious special fundraising agenda."

Currently, the medical center has construction plans which include a major modernization of its hospital, new construction for a consolidated new children's hospital at Stanford, and for programs in nuclear magnetic resonance imaging, and molecular and genetic medicine.

The specifics of the fundraising agenda for the medical center are under review, and will be going for approval to the university board of trustees sometime in the near future.

PROGRESS IN MEDICINE LECTURE SERIES SCHEDULED

STANFORD—

Advances in technology have enabled the medical field to take giant steps forward in the diagnosis and treatment of disease. The results of some of these will be described at Stanford University Medical Center's Fall Progress in Medicine Lecture Series.

"The Impact of Technology on Health and Disease" will feature three lectures on consecutive Wednesday evenings beginning Oct. 26. Following introductory remarks by Medical School Dean Dominick Purpura, Dr. Helen Blau, assistant professor of pharmacology, will describe how she and her colleagues plan to use genetic engineering techniques to help isolate the gene that causes muscular dystrophy. Blau's recent finding of an abnormality in the muscle cells from individuals with the disease has provided the necessary information to begin the search for the defective gene.

Development of an artificial ear is the topic of the second lecture in the series on Nov. 2. Dr. Blair Simmons, professor of surgery and otolaryngology, will discuss his techniques of electrically stimulating the auditory nerve, which he developed in conjunction with experts from the School of Engineering. Simmons is developing implantable devices that may restore hearing ability to the deaf.

The final lecture, to take place Nov. 9, will feature a new diagnostic tool that can provide more information for soft tissue than any now commonly used. Dr. Stuart Young, associate professor of radiology, will describe how nuclear magnetic resonance can improve diagnosis of disease. Young's new book, *NMR Imaging: Basic Principles*, is scheduled for publishing in early November.

The lectures are scheduled to begin at 7:30 p.m. in Sherman Fairchild Auditorium. They are free of charge and open to the public. Seating is limited. For information, call (415) 497-6389.

GLAUCOMA DETECTION UP TO TWO YEARS EARLIER WITH NEW DIAGNOSTIC TECHNIQUE

STANFORD—

Stanford ophthalmologist and a photographer have pooled their expertise to improve a new diagnostic technique that may detect glaucoma up to two years earlier than standard methods.

Glaucoma, a genetic abnormality of the eye affecting 2-3 percent of the population more than 40 years old, is characterized by loss of peripheral vision and eventual blindness if not treated.

With current diagnostic methods, the disease cannot be undoubtedly detected until individuals have started to lose their peripheral vision, said Dr. Louis Roloff, clinical assistant professor at the Medical School.

He's working on the technique with Jim Taskett, manager of Stanford's photographic services. By photographing the optic nerve fibers, one million hair-like strands lining the back of the eye that are responsible for vision, Roloff may be able to detect as little as a ten percent loss of fibers. This information is enough to begin treatment for glaucoma, arresting the disease years before the patient's visual field is impaired.

Current diagnostic methods include measuring the amount of pressure in the eye, the loss of visual field, and the increase of the optic cup size due to loss of optic nerve fibers.

Glaucoma is caused by "faulty plumbing." The eye makes its own nutrient liquid, Roloff explained. When an individual has the disease, the liquid cannot be eliminated as fast as it's manufactured. The condition is not curable. However, it can be controlled by administering eye drops that either open up the eye's drainage system, so the liquid can drain out faster, or slow up the manufacturing process.

Roloff and Taskett, who have been experimenting by photographing the nerve fibers for about nine months, perfected their technique using a special fundus camera to photograph the back of the eye through a dilated pupil, a special filter that produces red-free light to increase contrast, and a technical film with a high resolution and a low grain. The key, they felt, was to get as high a contrast as possible, in order to be able to detect the tiny nerve fibers as well as possible.

"Many others have tried to achieve this quality of photograph, but no one has been able to get consistently as good a picture as we have," Roloff said.

"I read the research on this type of photography," Taskett added, "and found that other researchers were using film, developing and printing methods that were giving them grainy, low contrast photographs."

Perfecting the technique is only the beginning, Roloff cautioned. His next goal is to provide proof to his fellow ophthalmologists. The ideal, he said, would be to follow patients he suspects may be developing glaucoma over time, photographing their nerve fiber loss and comparing it with the current diagnostic measurements. One problem, he explains, is an ethical one.

10/4/83 -more-

"I have one patient whose pressure was barely above normal, the cupping of his optic nerve was suspicious, and visual fields were normal. But the photographs showed he had already lost an estimated 20-30 percent of his nerve fibers," Roloff explained. "I would have liked to withold any treatment, and follow his progression over time. But ethically I can't do that. I've started treating him for glaucoma."

"It'll take up to three years to prove," he said. "But the photographs are impressive. They allow us to see even a small percentage of nerve fiber loss, whereas until now, the only test available were the patients' visual field and eye pressure.'

Other problems exist. "You just can't get a good picture of all patients," Roloff lamented. "Either they won't sit still, or their pupil won't dilate enough, or a cateract prevents enough light from getting in." Yet he estimates the technique will work for up to 75 percent of the patients who should undergo the test.

Despite the difficulty of obtaining research data to prove his technique, Roloff is encouraged by the enthusiasm of his colleagues. The photographs received a prize from the Ophthalmic Photographers Society, and will be included in a scientific exhibit at the American Academy of Ophthalmology's annual conference in November.

And, Stanford's ophthalmology clinic plans to begin using the diagnostic technique for its patients by the end of the year.

While he's still working towards large-scale acceptance of the basic idea, Roloff is looking towards future improvements of the technique. "Visual interpretation of the photographs may be too subjective," he explained. "If we could computerize the information, and quantitate the changes that would occur over a period of time, the loss of nerve fibers could be standardized so all ophthalmologists could understand exactly what it represented."

NEW DIAGNOSTIC METHOD REDUCES NEED FOR BLADDER CATHETERS

STANFORD—

Thousands of Americans may be freed from a painful dependence on catheters because of a new ultrasound technique which is unlocking secrets about anatomy of the bladder, Stanford researchers report in the October issue of *Seminars in Roentgenology*.

The research offers help to victims of spinal cord injury accidents, as well as hope for elderly patients now confined to nursing homes because of incontinence, said Gerald Friedland, professor of radiology at Stanford.

Friedland and Inder Perkash, who is the Paralyzed Veterans of America Professor of Spinal Cord Injury, have used ultrasound to achieve longer, more detailed looks at the human bladder and the surrounding areas of the abdomen. Friedland said this has accomplished two goals heretofore unobtainable with X-ray scans:

First, the researchers have learned some new generalities about human anatomy which should apply to many of the 25 million Americans suffering from previously untreatable bladder problems. Secondly, the accuracy of ultrasound allows safer and more detailed diagnosis of individual patients, so that drug treatments and surgery can be tailored more specifically.

"This diagnostic method is of immense value to any patient with a bladder defect caused by a breakdown in communication between the nerves and muscles which control the organ's function," said Perkash. Such patients include about half the diabetics older than 50, all patients with multiple sclerosis, and many elderly patients who suffer from a variety of vascular diseases. "In the last year, ultrasound diagnosis has already saved more than 200 spinal cord injury patients here from the pain and discomfort of catheterization," he said.

The catheter, a one-foot-long tube threaded up through the urethra to drain the bladder, is necessary initially for persons whose bladder goes into shock and fails after a spinal cord injury. After several weeks, some patients are able to empty their bladders by pressing firmly against the abdomen with their hands.

But often the technique didn't work for unexplained reasons, and patients became slaves to catherization.

The new ultrasound method, which involves a rectal probe and high frequency sound waves, provides a high degree of diagnostic accuracy never before obtainable, said Perkash. Through ultrasound scans, he and Friedland found that because of the way the bladder is positioned in the body, continuous pressure actually closes the urethra, trapping the urine. The solution? Patients were taught to tap rather than press their abdomen, relaxing the muscles around the urethra so that urine could pass easily.

In other patients, catheters inexplicably stopped working after several weeks of intermittent use. Through ultrasound scans, Perkash found a ledge-like flap of tissue that developed because the catheter irritated the bladder wall. This flap, which does not show up in conventional X-rays, can easily be removed via surgery once identified by ultrasound. Another application for the technique will be found in diagnosing congenital bladder problems in children, Perkash said. Many such problems, which can lead to kidney failure and death, are probably caused by abnormal flaps of tissue, undetectable in X-ray, but present in the infant urethra at birth.

Friedland and Perkash first noticed the value of the ultrasound scans when examining patients at the Spinal Cord Injury Service which Perkash directs at the Palo Alto Veterans Administration Medical Center. Modern physicians try to minimize the use of catheters in these patients because of the relatively high risk of infection, Friedland said.

"A recent study suggests that as many as 56,000 people die in the United States each year as a result of (an infection stemming from) catheterization," he said. For the 10,000 people each year who sever their spinal cords in accidents, an alternative to catheterization is of inestimable value, Friedland said.

Perhaps most important to these accident victims, who tend to be young men, the new ultrasound scanning method provides as much or more diagnostic information as conventional X-rays without the exposure to radiation. Recent studies by Perkash indicate that about 80 percent of all paraplegic and quadraplegic men are potentially capable of fathering children, and should not be exposed to radiation doses that can genetically damage sperm.

"So that no one gets too much radiation, we normally only run the conventional X-rays for about 30 seconds," said Friedland. "But with this (ultrasound) machine, if we really want to study some patients thoroughly and learn a lot about their condition, we can run it a long time with no ill effects at all."

Speed and low cost are two other advantages of the new scanning method over conventional X-rays in diagnosing and monitoring bladder problems, said Friedland.

"The conventional X-ray machine cost $350,000, but the new (ultrasound) machine is only $50,000. Most of the imaging devices being developed now are ever more expensive," he said. "This is the first time, to my knowledge, that we've developed a new diagnostic exam that is a lot cheaper."

"There are plenty of these specialized ultrasound machines available in the United States now," said Perkash. "But people have only been using it to look at the prostate. We are the first to use it for this purpose, and we're trying to get the word out to other spinal cord injury centers, and to any patient who has bladder dysfunction due to a neurologic disorder."

INNOVATIONS IN TREATING HEART DISEASE: A CONFERENCE

Editors note: Science writers who wish to cover this event should arrange to attend as guests by calling the medical center news bureau, at the number noted above.

STANFORD—

A two-day international symposium on such wide-ranging approaches to treating heart disease as heart and heart-lung transplantation, the artificial heart, and lasers, will be held at Stanford University Medical Center (SUMC) Nov. 18 and 19, 1983, in the Fairchild Auditorium.

Geared towards physicians, "Innovations in the Treatment of Cardiovascular Disease: 1984" will feature such Stanford and guest faculty speakers as Dr. William DeVries, artificial heart pioneer from the University of Utah; Dr. Donald Harrison, chairman of cardiology at SUMC and symposium co-director; and Dr. Norman Shumway, U.S. transplant pioneer and chairman of cardiovascular surgery at SUMC.

Program director is Dr. Robert Ginsburg, a clinical assistant professor of medicine in cardiology at Stanford, who recently reported initial success in clinical laser trials for the treatment of vascular disease.

Designed to provide a comprehensive update of recent research and treatments, the conference will also cover such topics as streptokinase for heart attacks, percutaneous transluminal balloon angioplasty (a widely accepted treatment), and other therapeutic modalities.

The symposium is sponsored through an educational grant by Cooper Medical Corporation of Mountain View. Advance registration is required, enrollment is limited to 300 participants, and a fee will be charged.

For enrollment applications or further information, call (415) 497-7587.

HEWLETT FOUNDATION FUNDS UNIQUE HOUSING PROJECT

STANFORD—

The William and Flora Hewlett Foundation of Menlo Park has given a $3,725,000 grant to the Assistance League of Santa Clara County to finance construction of a 42-unit building on Stanford lands near the University Medical Center for short-term lodging of out-of-town patients and their families.

The building will be named after Flora Lamson Hewlett, the late wife of William R. Hewlett and one of the founders of the foundation.

The building will provide short-term accommodations at low cost for families of hospitalized patients, cancer outpatients, potential heart transplant recipients, as well as other out-of-town patients—or family members accompanying them—who come to Stanford Medical Center for treatment periods of weeks or months.

The building will be owned and managed by the Assistance League, a national non-profit volunteer service organization, in a unique cooperative partnership between Stanford University and the League.

Stanford will provide the land and will finance design and planning for the building. The Assistance League, through the Hewlett Foundation grant, will cover costs of building construction.

Current plans are to build the structure on a five-acre site at the corner of Welch Road and Pasteur Drive.

Under an agreement worked out between Stanford and the Assistance League, the grant funds for building the short-term housing complex will be turned over to Stanford, which will supervise construction.

Stanford University President Donald Kennedy said, "This arrangement is unique in Stanford's history...It is the first time that a community organization has joined with the University for the common goal of easing the financial and emotional needs of people in affliction. The magnificent gift from the Hewlett Foundation will go far toward alleviating one of the most grievous problems facing those who come to Stanford Medical Center for treatment, or who accompany those in need of care."

Roger Heyns, President of the Hewlett Foundation, said, in announcing the grant, that "the Foundation is pleased to be able to support this very worthy project. The building will be a fitting memorial to Mrs. Hewlett's memory."

-more-

November 29, 1983

In acknowledging the grant, one of the largest ever given to an Assistance League chapter, Kay Clair, chairwoman of the League's HOME (Housing of Medical Emergencies) project said, "All our members who have worked so hard to make this happen are delighted. It is a dream about to become a reality."

The Assistance League will own the building, and will also furnish, oversee, maintain and manage the units. A full-time manager employed by the League will occupy one of the units.

Screening and selection of potential occupants will be carried out according to need by social workers in Stanford Medical Center's division of social services. Occupancy of the units will be reserved for those coming from outside a 50-mile radius of the medical center, and stays will be limited to nine weeks, usually at the rate of $10 per day.

Cancer outpatients who must undergo a course of radiation therapy over a period of weeks, and potential heart transplant recipients awaiting donor organs represent two large groups of patients likely to be helped. Out-of-town families of hospitalized patients in neurology, oncology, pediatrics and other medical specialties also will make use of the inexpensive housing.

Stanford planners and members of the Assistance League worked together on design for the building, explained Jeanne Kennedy, director of community relations for Stanford University Hospital. Kennedy has worked with the League for several years in planning the project and continues to serve as project liaison between Stanford and the League.

Clair describes how the Assistance League's HOME project got its origins. "Many of our members had personal experiences with family and friends with cancer. Being at the hospital day after day, seeing relatives in the waiting rooms, we became aware of the desperate need for patient and family housing near the hospital."

The patients' plight spurred HOME project volunteers to undertake a study of housing needs for Stanford patients and their families in 1976. They discovered that competing demands from diverse groups in need of housing—students, Silicon valley, retired people—have made short-term rentals in the Peninsula area extremely scarce and expensive.

Some motels offer weekly rates but few conveniences, noted Clair. Even then, she added, "the cost of staying in a motel for weeks on end, renting a car to go back and forth to the hospital for daily treatments, and eating out several times each day can be astronomical."

Local apartments tend to be unavailable or have leasing requirements that are infeasible, she explained. And finding rooms in private homes has not been successful, Clair reported, because "even the most generous people are unable to cope with serious illness in their home for any length of time."

After many months of investigation, in 1979 the HOME volunteers leased two one-bedroom apartments in the Oak Creek apartment complex near Stanford Hospital, and began offering nine-week rentals to families and patients at the $10 per day rate. Soon, they acquired two more Oak Creek units for their program.

-more-

All four units have since experienced 100 percent occupancy, with many families on the waiting list, Clair said. In the four years since the program began, more than 150 families have been helped by the subsidized housing, she added. But this is "just a drop in the bucket compared to the need," Clair noted, predicting that the new building would easily achieve 100 percent occupancy as well.

Current plans envision a 4-story building at the proposed 1100 Welch Road site. Each of the 42 units will consist of a bedroom, living room, kitchen, and bath, averaging 570 to 600 square feet, with furnishings to accommodate two people. Two units will be equipped to handle physically disabled individuals, and other units could be similarly adapted, if necessary, Jeanne Kennedy said. Communal lounges and laundry facilities will also be provided in the complex.

The 1100 Welch Road site is one of two parcels that made up the proposed Stanford West housing project. Stanford West was postponed indefinitely in September after the Palo Alto City Council attached conditions to its approval that were unacceptable to the University.

Frank Morrow, Stanford's director of real estate, said that the University has decided to proceed with the units at 1100 Welch Road as a separate project. It will include the structure for short-term lodging, and 100 to 150 apartments or limited equity coop units for nurses, interns, resident physicians and other staff at the Medical Center. Both buildings were part of the original Stanford West proposal.

Construction of the buildings could begin in 1984, Morrow said, and would require 16 to 18 months to complete. The remainder of the original Stanford West project—housing on a 46-acre site across Willow Road—has been delayed pending additional design studies and discussions with Palo Alto about the conditions it has required, Morrow said.

The twenty or so members of the Santa Clara County chapter of the Assistance League who have worked on the HOME project are thrilled by the Hewlett Foundation grant, said Clair. Most of the chapter's regular funds are raised through its Los Altos-based Costume Bank. Chapter members come from all over the county, including Saratoga, Los Altos, Cupertino, Sunnyvale, Mountain View, San Jose and Los Gatos, Clair said.

But to no one will the grant have greater meaning than to the patients and their families, Clair remarked, citing a poignant letter recently addressed to the Assistance League by a relative who had used one of the Oak Creek apartments.

The letter said, in part, "I want to express to you, however inadequately, how very much it meant to us to have the use of this lovely apartment during the last weeks of my husband's life. He died Wednesday without receiving the heart transplant for which he had come. To go to the hospital in the middle of the night or to return from a late night vigil was eased because of love on your part, and we thank you for it."

FUTURE DIRECTIONS IN TREATING HEART DISEASE

STANFORD—

EDITORS: The following story covers some highlights of a recent conference on future directions in the treatment of cardiovascular disease. The release is intended to provide you with some background or with story ideas. For further information, or for copies of selected reprints that provide further detail, contact the News Bureau at (415) 497-6911.

In the future doctors will use lasers to vaporize cholesterol buildups in the arteries, implantable pumps to boost ailing hearts, and drugs that dissolve blood vessel clots in the fight against cardiovascular disease, leading heart specialists predicted November 18 and 19 at a Stanford University School of Medicine cardiology conference.

Balloons that squash cholesterol blockages in blood vessels, implantable devices that can halt life-threatening heart rhythm disturbances, and better drugs for controlling chest pain are also on the cardiology horizon. These are among the exciting new approaches to heart disease outlined to over 350 participants—including doctors, nurses and representatives of biomedical industries—who attended the educational conference, "Innovations in the treatment of cardiovascular disease: 1984."

New methods for treating heart disease owe much to developments in more basic sciences such as physics, chemistry, and engineering, said Dr. Donald Harrison, chief of the division of cardiology at Stanford and a co-director of the conference. Although the new advances "must be brought into clinical practice rapidly," he said, their safety, efficacy and cost-effectiveness first must be thoroughly studied and documented in carefully designed clinical trials.

Most of the therapies discussed at the symposium are still in these experimental stages and therefore are only available under special clinical programs at research medical centers.

The most avant-garde technique described at the conference is the use of lasers to vaporize plaques that obstruct blood flow in arteries leading to the heart and legs. Most of the Saturday sessions were devoted to discussions of this very preliminary work in applying laser energy to problems in cardiology. The laser procedure, called laser angioplasty, has thus far been performed on only ten patients worldwide.

The technique employs an argon laser whose highly focused light beam emerges from the tip of a catheter. (A catheter is a long, flexible tube that can be threaded through the patient's blood vessels.) A catheter is inserted into the patient's circulatory system through a puncture in the groin or arm and eased through the blood vessel to the site of blockage. Once in place, short bursts of the intense laser light burn the obstruction away, restoring blood flow.

November 21, 1983 -more-

Dr. Robert Ginsburg, clinical assistant professor in cardiology at Stanford, and also the symposium coordinator, reported on Stanford's experience treating five patients with severe arterial blockages in the legs. Dr. Daniel Choy of Lenox Hill Hospital in New York, described his treatment of five patients with coronary artery blockages.

The greatest risk of using laser light in blood vessels is that the intense heat could perforate an artery wall, Ginsburg explained. In none of the patients undergoing the procedure did this occur, demonstrating that the technique can be applied safely, he said. However, the treatment was not effective in all ten patients in whom it was tested, the laser researchers reported.

Laser therapy for blocked arteries is attractive because it could offer an alternative to surgical approaches such as coronary bypass or limb amputation, the doctors said. But it is also so new that its usefulness is far from certain, they stressed. "It will take several years of testing in patients, as well as improvement in the laser delivery systems before we will know the true efficacy of this technique," Ginsburg said.

Balloon dilatation catheters, which have been undergoing clinical testing since 1978 in the U.S., are more versatile and less expensive than laser treatment, said their inventor, Dr. Andreas Gruntzig of Emory University in Atlanta.

A balloon catheter has a small sac of compressed rubber at its tip that can be inflated with air at the site of a blood vessel blockage. Inflation of the balloon compresses the plaque of cholesterol and reopens the arterial channel. The balloon is then deflated and withdrawn.

Initially after its introduction five years ago, the procedure was tested only in peripheral blood vessels in the legs and in the largest coronary arteries. But as doctors gained more experience in its use and as more sophisticated devices became available, some research centers began testing the balloon dilatation procedure in smaller coronary arteries, with considerable success.

Dr. Geoffrey Hartzler of the Mid-America Heart Institute in Kansas City, reported results of clinical trials in which the balloons were able to reopen multiple coronary vessels in 92 percent of patients who underwent the procedure, with 86 percent of those followed for 10 months remaining asymptomatic.

"There is a tremendous explosion of technology in this area," Hartzler said. "Advances are made weekly."

Around the country, as many as 8,000 patients may have undergone balloon dilatation therapy since its introduction in 1978, said Dr. Edwin Alderman, associate professor in cardiology at Stanford. Although it is still an experimental procedure, it is becoming an accepted alternative to coronary bypass in certain types of patients, particularly those with one major narrowing. Among the advantages of balloon dilatation (also called "percutaneous transluminal coronary angioplasty," or PTCA) over surgery are reductions in expense, hospitalization time, and risk.

-more-

During a heart attack, blood flow to the heart may stop because clots form in vessels obstructed by cholesterol buildup. An enzyme called streptokinase was introduced in the late 1970s that can dissolve the life-threatening clots and help save heart tissue from irreparable damage.

A major study carried out in Washington state in 14 hospitals over a period of almost two years suggests that streptokinase may improve patients' chances of longterm survival following a heart attack. Dr. J. Ward Kennedy of the University of Washington, reported that a higher percentage of the patients treated during heart attack with streptokinase were alive six months following their attack than were similar heart attack victims who did not receive streptokinase.

However, use of the anticoagulant drug does involve risks, most notably the danger of uncontrollable bleeding. Several conference speakers debated the safest and most effective way of administering streptokinase: directly to the site of a clot in the heart by means of catheter, or intravenously by an injection.

Dr. Peter Rentrop of New York's Mount Sinai School of Medicine advocated direct delivery of streptokinase to the heart vessels, which must often be followed by balloon dilatation or another procedure that then removes the cholesterol plaque. The risk of severe bleeding in other parts of the body is much higher if the drug is given intravenously, he said. "Both methods of intervention are still investigational," he stressed.

Conference participants also heard about Stanford's heart transplantation program which has placed new hearts in 312 patients in 16 years. Dr. Edward Stinson, director of the transplant program, noted that while approximately three patients each month receive new hearts at Stanford, the demand for donor hearts is far greater and many potentially transplantable patients die due to donor organ scarcity.

Thanks largely to the introduction about two years ago of a new anti-rejection drug called cyclosporine, one-year survival rates have improved for heart transplant patients, Stinson observed. Whereas about 60 percent of patients survived one year after transplant using the older immunosuppressive drugs, 81 percent receiving cyclosporine achieve post-transplant survival of at least one year.

Cyclosporine also made possible for the first time successful transplantation of the heart and lungs together in one operation. Since March, 1981, doctors at Stanford have performed 16 such operations, reported Dr. Stuart Jamieson, assistant professor of cardiovascular surgery. Eleven of those patients remain alive and nearly a dozen patients are waiting to undergo the procedure, he said. However, lack of donor organs means that "we lose someone who is waiting about once every month," Jamieson noted. "The main problem in heart-lung transplantation is donor procurement," he rued.

Because donor organs for transplantation are so scarce, there is considerable interest in developing artificial devices that could boost, or even replace, ailing hearts, said Dr. Philip Oyer, associate professor of cardiovascular surgery at Stanford. Oyer reported on implantation of left ventricualr assist devices (LVADs) in calves, with survival rates of approximately six months.

The LVAD under development by Oyer and colleagues is about the size of a person's palm. It will be inserted in the patient's abdomen without external connections because electric power to drive the device will be transmitted through the skin using induction coils. The pump is designed to supplement the patient's own heart until a permanent donor organ is available. This could help as many as 5,000 patients with endstage heart disease every year in the U.S., Oyer said.

Although the device has operated successfully in animals, clinical trials in humans are still several years away, according to Oyer. "Although a workable device now exists, substantial problems remain before use in humans is advisable," he said.

-more-

Dr. Lyle Joyce, a member of the team that implanted an artificial heart in a patient last year at the University of Utah, reviewed that clinical experiment which drew worldwide attention. Dr. Barney Clark, the 61-year old patient who received the artifical device, survived 112 days while the world watched, Joyce recalled.

"Unfortunately, most of the world thought Dr. Clark was being kept alive by the pump and that he was existing in a vegetative state. That wasn't the case," Joyce stated. Although his postoperative course was rough, requiring the intervention of doctors from 21 different areas of medicine, "Dr. Clark walked through the hospital and enjoyed another Christmas, New Year's, birthday and anniversary with his family that wouldn't have been possible otherwise," Joyce claimed.

If Clark's medical condition prior to the implant had been more favorable, the device could have been expected to keep him alive for over a year, Joyce said. Joyce reported that the Utah artificial device is constantly undergoing improvement. He predicted that further experimental implants will be done on humans, and that eventually thousands of patients with endstage heart disease who can't get transplants would be the beneficiaries. "We believe the artificial heart is here to stay," he concluded.

Patients who have abnormal heart rhythms may be helped by another experimental implantable device discussed at the conference. The automatic internal defibrillator can sense certain undesirable rhythm disturbances and deliver a strong electrical jolt that shocks the heart back into a normal beating pattern, reported Dr. Roger Winkle, associate professor in cardiology at Stanford.

The device, which is a little larger than a pack of cigarettes, is implanted in the abdomen and its electrical leads rise to the heart.

Winkle said that it is being tested in patients who are at high risk of sudden death from arrhythmia and who are not helped by more conventional therapies. However, it will probably only be a backup therapy and never completely replace other treatment modes, Winkle added. At Stanford, about 50 patients have been fitted with the defibrillators and are being monitored to determine the efficacy of the device, he said.

Other topics discussed at the conference included the promising anti-arrhythmic drugs called calcium blockers. Also noted were improvements in another class of cardiac drugs, the beta blockers, commonly prescribed to alleviate pain from coronary artery disease. The beta blockers also show promise in reducing risks of second heart attacks in patients with cardiovascular disease.

The conference was sponsored by the division of cardiology at Stanford University School of Medicine, with an initial educational grant from Cooper LaserSonics, Inc.

IMMUNOSUPPRESSED PATIENTS SHIFTED TO AID INFECTION CONTROL

STANFORD—

Future heart and heart/lung transplant patients at Stanford will temporarily be diverted from the cardiac post-surgical intensive care unit because of the potential risk of Legionella infection.

James F. Silverman, Stanford University Hospital (SUH) chief of staff announced the new patient placement policy on Friday, because of several recent cases identified among patients transplanted since February 1982. No deaths have been attributed to Legionnaire's Disease, he said.

"It is a given that transplant patients, because of the antirejection drugs they take, have extremely vulnerable immune systems and are susceptible to a wide variety of ailments which don't affect the general public. However, when we believe that we have a potential way to reduce even one of those risks, we feel we ought to take it," Silverman said.

He said no cases of the disease, easily treatable with an antibiotic, have been reported among staff or non-transplant patients in the unit, since their immune systems are intact.

Silverman said the decision, which does not affect non-transplant cardiac patients or transplant patients currently on the unit, followed recommendations at a Friday meeting by a Task Force on Care Review/Risk Management, comprised of physicians, nursing personnel and administrators.

Dr. Lucy Tompkins, director of the Diagnostic Microbiology Lab, said Legionella has been detected in a sampling of the water heater supplying the affected unit where transplant patients are taken immediately after surgery. On Oct. 29, the water temperature was increased to a level expected to kill the Legionella bacteria. However, subsequent samplings have indicated small quantities of bacteria, she said.

Infection control personnel have speculated that the disease is transmitted to vulnerable patients from water vapor escaping from hot water faucets, or transmitted from equipment or hands which have been washed in the contaminated water and then placed near an airway or other opening on the patient.

Legionnaire's Disease is a type of pneumonia caused by a newly discovered bacterium. It accounts for a certain percentage of pneumonia cases which previously were ascribed to other bacteria and viruses, Tompkins said.

-more-

NOV. 21, 1983

Although the exact number of cases which have affected Stanford transplant patients may not be known, in recent weeks tallies were completed confirming nine cases among patients transplanted since February 1982, said Tompkins. She said undetected cases may have been occurring since the transplant program began in 1968, but the sophisticated and newly developed test procedures needed to detect the malady were not available at SUH until last June. Some of the diagnoses were made retroactively from serum kept in research laboratories, she said.

"We want to make it absolutely clear that we are not talking about an epidemic or possibly even an increased number of cases," Silverman said. "Quite basically, our increased ability to detect this condition has given us a better handle on ways to control infection in the hospital," the chief of staff added.

The diversion of patients would continue until the source of the bacteria could be definitely determined and corrective action completed, Silverman said.

Laurie Gunderson, clinical nursing coordinator in the cardiac intensive care unit, said up to four rooms in two other intensive care units in the hospital would be specially equipped to handle future transplant patients. The transplant nursing team would be available to care for the patients, who normally remain from five days to three weeks in intensive care after surgery.

Two transplant patients currently undergoing treatment in the cardiac surgical intensive care unit will remain until they are ready for discharge to a less acute area. Neither patient has shown any sign of Legionnaire's disease, Tompkins said.

In a memo to the cardiac intensive care staff, Gunderson and Care Review Coordinator Betsy Collins said, "The risk for Legionella is only to immunocompromised patients. Medical or nursing staff are not at risk for Legionella pneumonia."

Legionnaire's disease was first identified in the mid-70s following several mysterious deaths among American Legion conventionieers in Pittsburgh whose immune systems appeared to have been compromised by alcohol and tobacco.

Several other hospitals around the country have moved patients or temporarily closed down while the source of infectious agents are identified and action is taken.

Silverman said the Care Review/Risk Management Task Force currently is studying a variety of bacterial and fungal agents, common to the environment, which are particularly harmful to immunosuppressed patients.

AREA'S FIRST PEDIATRICIAN HONORED

STANFORD—

Dr. Esther Clark, life-long Palo Altan and pediatrician credited with founding the Children's Health Council, received the Stanford Medical Alumni Association first annual J.E. Wallace Sterling Distinguished Award Nov. 18.

Clark, who received her M.D. from Stanford Medical School in 1925, was honored at the alumni association's annual fall reunion. She was presented with the award by Sterling, a former Stanford University president.

"I was astonished and felt a sense of humility when I learned of the honor, Clark said. "I don't begin to deserve this, but I love it anyway."

Clark started practicing medicine in 1927, the first and only pediatrician between San Mateo and San Jose. Her practice changed with evolution of children's medicine. Clark experienced the revolutionary development of immunizations and antibiotics. She responded to and changed with the challenges of modern medicine and the pediatrician's attention to children's mental and emotional states as well as physical conditions.

This evolution was not without Clark's influence. A few of her "babies" included the Children's Health Council (CHC), which just recently celebrated its 30th anniversary, and the Child Accident Prevention Committee, established by the American Academy of Pediatrics upon her suggestion.

Even as a young girl growing up in Palo Alto, Clark knew she wanted to be a physician. After completing her education at Stanford, she interned at San Francisco General Hospital. She then completed her pediatrics residency under the famed Dr. Harold K. Faber at Stanford. At 27, she returned to Palo Alto to join an internist and two surgeons to pioneer not only the practice of pediatrics but also the concept of group practice.

In a recent interview, Clark reminisced about the early years of practice. Because there was rarely a specific cure for most of the diseases she saw, she said, "we simply had to let the patients get well with the best advice and medications we could give them." She helped campaign for immunization against smallpox, diphtheria, whooping cough, and tetanus. By 1937 the city's infant death rate had dropped significantly, and newspaper articles credited Clark with making Palo Alto "the safest place in the world for a baby to be born."

-more-

11-21-83

This was perhaps just one of the contributions that prompted the Palo Alto Chamber of Commerce in 1981 to honor Clark with the Distinguished Citizen Award "in recognition of exemplary leadership and significant professional contributions of lasting benefit to the Palo Alto-Stanford community."

By the war years the group practice had expanded to form the nucleus of what is today the Palo Alto Medical Clinic. The area's population boomed, and Clark remembered seeing up to 80 patients in the office, and up to another 20 on house calls.

The pediatrician's role boomed as well. Once children were brought to a physician only because they were ill or hurt, she recalled. "Now we have wholesome family and widespread commitments to prevention of many of the diseases of young children. With the development of specific and preventive treatments for most acute illnesses, we have become aware of the needs for the overall functioning of the child," Clark said.

It was this belief that led to the establishment of the CHC. What started as a center for rehabilitation of retarded children became known as the only facility of its kind working to "habilitate" and rehabilitate children on an outpatient basis. CHC today is a diagnostic and treatment facility for children with learning and emotional disabilities.

"We provide children's services that aren't met anywhere else in the area," she explained.

By the 1950s Clark recognized another need that seemed to be going unmet: that the leading cause of childhood deaths was, and continues to be, accidents. This led to the Child Accident Prevention Committee, and Clark spent four years serving on its initial committee.

Clark said she enjoyed her long practice in one area, which gave her a chance to treat generations of families. In addition to her private practice, she served as a clinical faculty member at Stanford Medical School since the early 1930s.

Since retiring from practice at the age of 72, Clark has focused on a variety of other interests. Her two rambling houses, one above the Stanford campus and one in Mendocino County, reflect her love of spacious and graceful architecture. A photographer since childhood, her walls are covered with her own photographs from her travels to Africa, the Galapagos Islands, the Orient, India, the South Pacific, New Guinea, Australia and Iran. Earlier this year, she took a cruise for the first time in her life, traveling through the Inside Passage to Glacier Bay.

"I started practicing medicine in the dawn of immunization," she said. "I've experienced more changes in the last 50 years in the medical field than ever before. Many diseases have been wiped out, and people are living longer and better."

(Editors: The following story was transmitted to several Bay Area wire services and publications on 11/17

SIX HOSPITAL EMPLOYEES ARRESTED ON DRUG CHARGES

STANFORD—

Six Stanford University Hospital employees were arrested Thursday (Nov. 17) on drug related charges following a five-month investigation in which the hospital cooperated.

Palo Alto Police Sgt. Ron Schindler said the employees were arrested in various Peninsula locations after warrants were issued earlier in the week by a Palo Alto Municipal Court judge.

The detective said the six persons arrested appeared to have operated independently.

Sheldon King, director and executive vice president of the hospital, said none of the arrested persons was directly involved in patient care.

Booked for investigation of selling cocaine were Rommel Day, 27, Palo Alto, a food service worker; Craig Julien, 21, East Palo Alto, linen assistant; and Randy Creamier, a 22-year old operating room orderly from Mountain View.

Officers said they arrested Day at his home, and that Creamier and Julien were arrested en route from the hospital in Palo Alto.

Kirk Williams, 21, Redwood City, was booked for investigation of selling an undisclosed quantity of controlled substances. Officers said Williams was arrested in a hospital corridor.

Police Lieutenant Lynne Johnson said Williams was also booked for investigation of posessing stolen hospital property, including an over-the-counter analgesic.

David Cannon, 34, was booked for investigation of offering to sell a controlled substance from the pharmacy. Detectives said the substances included codeine, Talwin and Valium. Officers said Cannon was arrested as he drove into his carport.

Donald Utt, SUH associate administrator, said Cannon and Williams were technicians in the pharmacy with duties involving procurement of materials, not dispensing of medication to patients.

NOV. 18, 1983

-more-

Mike Robinson, 26, of San Carlos, a mail room clerk, was arrested and booked for investigation of selling a controlled substance, methamphetamine or "crank." In addition, police booked Robinson for investigation of possessing controlled substances, believed to be marijuana and methamphetamine, found at his residence at the time of his arrest.

Schindler said the investigation began last summer following information provided by hospital officials that isolated drug sales were being made to employees and visitors.

During the summer, he said, undercover agents from the Allied Agency Narcotic Enforcement Team of Santa Clara County bought or attempted to buy drugs and medications from the six arrested individuals both on and off the premises at SUH.

Johnson said Day "was one of the first people we were looking at in conjunction with this investigation. He was the jumping-off point for the entire probe."

All six persons were taken to Santa Clara North County Jail in Palo Alto, with bail ranging from $5,000 to $15,000 each.

Investigators would place no total value on quantity of materials taken from the hospital pharmacy.

Utt said the theft of controlled substances from the pharmacy would be reported to appropriate state and federal officials. The volume of material taken was being inventoried, Utt said. A representative of the State Board of Pharmacy has cooperated with Palo Alto police.

Carole Price, associate director, said the six employees would be suspended pending the hospital's investigation of the matter "from an employment context."

In a statement following the arrests, King said, "I'd like to emphasize that this investigation leading to six arrests was conducted with the full knowledge of Stanford University Hospital. We regret the situation, but I feel confident that patient care, our most important concern, was not compromised. While I believe that this situation was isolated, the thorough action of local law enforcement officials and hospital personnel should serve as a reminder that activities of this sort will be dealt with unambiguously."

Johnson emphasized that "the hospital cooperated fully in the investigation."

NUCLEAR MAGNETIC RESONANCE IMAGING PROVIDES PHYSICIANS WITH SUPERIOR DIAGNOSTIC TECHNIQUE

STANFORD—

Stanford physicians will soon be using a new imaging technique that provides more diagnostic information than ever before while being harmless and non-invasive, according to a Medical Center radiologist.

A temporary facility that will house one nuclear magnetic resonance (NMR) imaging system should be operational by Spring 1984, said Dr. Stuart Young during a public lecture Wednesday (Nov. 9) evening in Sherman Fairchild Auditorium.

Plans are also underway for a permanent center to serve as a base for the medical center's clinical and research programs involving NMR, the imaging method that allows physicians to see the soft tissue of the body more clearly and completely than any others, such as X-ray and CT—computer tomographic—scans.

NMR imaging has already been shown to be superior in diagnosing diseases such as multiple sclerosis, a degenerative central nervous system disease, Young said. It also allows physicians to see bone marrow for the first time ever.

"This is the one of the greatest medical developments of all time," he said.

NMR is based on the fact that nuclei, the core of atoms, carry electrical charges that respond to magnetism. Like tiny bar magnets, these nuclei vibrate when trapped inside a magnetic field.

The technique is based on the Nobel prize-winning discovery of Physicist Felix Bloch at Stanford in 1945. He found simultaneously with Harvard researchers a way to detect "resonance" in nuclei. The potential applications of this finding went unrealized for years by chemists and biologists. It wasn't until 1974 that Paul Lauterbur, professor of chemistry at the State University of New York, published the first image based on NMR, which he called zeugmatography.

To understand exactly how NMR works, Young explained, consider one of the body's most common substances. Like soldiers at ease, positively-charged hydrogen protons, particles in nuclei, spin around at random. By exposing them to a magnetic field, in NMR's case a giant doughnut-shaped magnet up to 40,000 times the strength of the earth's magnetic field, the protons snap to attention and align themselves with the magnet's charge. The alert protons can be tipped by zapping them with a specific radio frequency, providing energy absorbed by the protons. They hold onto the energy for varying amounts of time, depending on the type of tissue they make up. When they release the energy, righting themselves in the process, signals are emitted and picked up by the computers.

-more-

11/11/83

It's possible to tell which part of the body the signals are coming from, Young continued, because of the varying amounts of time the energy is held by the protons in the tissue. This lapse is known as the relaxation time. Fatty tissue, for example, has a short relaxation time, while cancerous tissue, physicians have found, has a long one. For imaging purposes, the computer assigns each a different hue, thus creating a picture of the inside of the body.

In addition to its other advantages, NMR imaging can present an image of any angle of the body, unlike CT scans that can only show a cross sectional slice, Young said.

The brain, for example, is much more visible than ever before because NMR penetrates through the bone at the base of the skull and the junction of the spine. Thus, NMR reveals brain tumors, tissue-killing blockages, and any infectious process.

Atherosclerosis is more easily diagnosed because NMR can detect fatty tissue building up to occlude the heart's blood vessels. The technique can detect cancerous lymph nodes in the lung area, not possible with more conventional techniques that fail to distinguish large blood vessels from enlarged lymph nodes. Physicians can also determine different types of cancer in the same area, Young explained, thus allowing more tailored—and subsequently more effective—treatment.

It's even easier to diagnose bone fractures, Young said, because the images show where blood has seeped into the bone area.

The temporary facility, to be located near the medical center, will allow physicians to begin using NMR imaging, Young said, until the $5.5 million NMR center, which is scheduled to house four magnets, is completed. And the Stanford University Hospital Modernization Project includes plans for a NMR unit that will house one magnet.

Because of the strength of the magnets, Young continued, a number of safety precautions have to be considered in constructing the NMR buildings. The magnets themselves must be inside rooms with specially built, shielded walls. THe buildings must provide a parameter of about 68 feet around the magnets. This has been established as the zone outside of which people will not be affected by the magnetic field.

To guard against any mishaps, the entrances to the buildings will be monitored by sensitive metal detectors, Young said. Anyone with any type of metal device, such as a pacemaker or even a screw holding a joint together, cannot come inside the 68 foot parameter.

Young acknowledged the $2 million price tag on the NMR imaging systems, but said he does not think this will lessen the demand for the magnets. "NMR can give so much more information than conventional imaging methods," he said. "Patients will seek out this harmless, no-risk technology that will give more information to allow earlier diagnosis and treatment of disease."

TOO SOON TO CHANGE DIABETIC—OR NORMAL—MENUS

STANFORD—

Recent research in diabetes and metabolism has raised many interesting questions, but is still too preliminary to apply to meal planning or alteration, contend investigators at Stanford University's clinical research center.

The team led by Dr. Gerald Reaven, professor of medicine and gerontology, is concerned that the diabetic public may be getting mixed messages from news accounts about what they should and should not continue to eat.

In recent decades diabetics have been taught about two classes of carbohydrates—the simple sugars and the complex starches. It was generally accepted that only refined sugars, such as those found in sweets, were off limits to certain groups of diabetics, since they were believed to cause large swings in blood glucose.

But now data collection has indicated a wide range of metabolic response to both categories of carbohydrates, making the standard distinctions seem obsolete and almost arbitrary, and leading to the introduction of a "glycemic index" to measure the body's glucose response to any given food.

According to the index, ice cream elicits almost no shift in blood glucose level, whereas a potato increases it drastically. Bread and rice also are found to raise blood sugar more than such foods as pasta and beans.

The problem with the measuring stick, Reaven said, is that although limited in scope, it is now being heralded by some as a major key to the planning of diabetic menus. He and colleagues Ann Coulston, M.S., R.D., and Clarie Hollenbeck, Ph.D., express their concerns in a letter to appear in the January 1984 issue of the *American Journal of Clinical Nutrition*.

The three have set guidelines for future studies in the field, so that factors such as nutritional balance, effects on plasma lipids, and insulin response, as well as glucose response, are taken into account.

Their letter is to appear simultaneously with one by Dr. David Jenkins of the University of Toronto, who has spearheaded much of the work leading to the new measuring tool.

"What's needed is to look at the overall metabolic response to a food, eaten in the context of a normally varied meal," said Coulston, who performed such a study recently at Stanford. "We found that the differences between carbohydrates, in terms of glucose response, are not as great when measured as part of a meal instead of in isolation."

11-7-83 -more-

"Going by the index alone," Hollenbeck added, "one would think diabetics should avoid certain groups of foods—foods which, in reality, may be beneficial."

Thus, another misconception the Stanford researchers want to dispel is that adult-onset diabetes may be caused by eating certain of the "wrong" kinds of carbohydrates, or that it may be cured by dropping them from one's diet.

Whether the glycemic index offers any potential therapeutic utility has not yet been established. Relying too much on it, they warn, may lead to short-sighted management of glucose response alone, ignoring insulin response entirely—despite the fact that the latter may be of more clinical significance, particularly in the non-diabetic population.

"Increased insulin levels have been shown to increase risk factors for the development of heart disease," Hollenbeck said.

Some of the initial studies leading to use of the index were conducted at Stanford. Reaven collaborated in 1977 with then CRC dietitian Phyllis Crapo and postdoctoral fellow Jerrold Olefsky, both now at the University of California School of Medicine in San Diego.

The three conducted preliminary trials which were valid, Reaven said, as far as they went, but which have since been improved and expanded upon as new data results came in. "Unfortunately, the initial findings were prematurely presented and misinterpreted in a *Science* magazine article."

"In a similar way," said Coulston, "the press has recently suggested that some simple carbohydrates and refined sugars, such as sucrose, may *not* need to be avoided in the diabetic's diet. But this assumption was based on one-meal studies.

"We are just now beginning to examine more long-term effects," she concluded, "and it's becoming clear that even very small changes in dietary sucrose may, without increasing glucose response, still lead to significant elevations in insulin and lipid concentrations.

"In light of this, it seems obvious that we need to learn more about this before advising patients with metabolic disorders that sucrose intake is irrelevant to their health."

Many of these issues, the researchers point out, are significant not only for diabetics, but also for the public at large, since a better understanding of metabolic response to different foods should lead to better dietary advice for all.

But it is still too soon to know just how many of the findings in normal and mildly diabetic subjects can be applied to the severely diabetic population, and vice versa.

FOR IMMEDIATE RELEASE

CARDIAC TRANSPLANT GRANT RENEWED FOR FIVE YEARS

STANFORD—

Stanford University Medical Center has received $7.85 million in research funds from the National Heart Lung and Blood Institute (NHLBI) for continued research and clinical trials of heart and heart/lung transplantation during the next five years.

The NHLBI has supported the program since shortly after the first heart transplant was performed at Stanford in January 1968. The most recent grant, announced officially in October, is retroactive to May and will extend for five years until April 30, 1988, said Dr. Edward Stinson, head of the cardiac transplant program at Stanford.

Stinson said researchers hope to concentrate their efforts on developing the combined heart/lung operation, which has been performed 15 times since March 9, 1981, and on better methods of preventing the body from rejecting someone else's heart. Included in the latter research is an effort to understand and perhaps alleviate the side effects caused by antirejection drugs.

During the current funding period, Stinson said he hopes that heart-only transplantation, already demonstrated to be lifesaving and therapeutic for some patients, will be routinely paid for by insurance companies.

"By the end of the next five years," Stinson said during a recent interview, "I hope that it is universally accepted within the health industry of this country that isolated heart transplantation is a reasonable, efficacious and therapeutic procedure deserving of full reimbursement from all types of third-party carriers."

The transplant procedure currently is in state of reimbursement uncertainty without industry-wide standards, said Stinson, a professor of cardiovascular surgery. Medicare's parent agency--the Health Care Financing Administration--has not yet determined that heart transplants are suitable for reimbursement.

Limited money from the federal grant had been available to pay some patient costs not covered by insurance. But even this money is being phased out during the current five-year budget, Stinson said, leaving insurance companies and other third-party payers with an even more important role than ever in paying patient costs.

Current survival rates, Stinson noted, are 81 percent for one year and 71 percent for two years among the more than 80 patients transplanted since a new anti-rejection drug, cyclosporine, began to be used on all patients after December 1980. Cyclosporine appears to control rejection of transplanted organs more effectively than anything used before, and unlike its predecessors, cyclosporine leaves intact much of the body's immune system or ability to fight off infection.

Nov. 1, 1983

-more-

Cyclosporine recently was granted tentative approval by the Food and Drug Administration. Consequently, Stinson believes that many hospitals with open heart surgery capabilities will begin performing transplants in the next few years. For these centers, Stinson offered some caution:

"I hope that only centers that have the necessary expertise and seriousness about performing heart transplantation become involved. In other words, there is a great temptation on the part of many people to become involved in heart transplantation on a superficial level for geopolitical and other types of reasons, and that is to be deplored."

Widespread transplantation occurred soon after the first human heart transplants were performed. Most patients died very quickly, and by the early 1970s, only Stanford and one or two other medical centers continued the operation.

"The success of Stanford's past record," Stinson said, "resulted in large part from a tremendously extensive laboratory experience. That in turn prepared us for many of the complexities involved in the field and led directly to the ability to perservere."

h the passing of years, it is apparent to Stinson that cardiac transplantation is ready to move from a handful of research centers such as Stanford into widespread clinical use.

"Now it's a different ballgame," said Stinson, and expansion is possible because much of the procedure is standardized and removed from the realm of the experimental. Stanford physicians have published details of the surgical procedure, and the techniques follow an established procedure, he said.

Perhaps revealing about the direction of transplantation is what is not going to be emphasized during the next five years.

"There's little physiology in terms of isolated heart replacement," Stinson explained. "The operation is standardized, early post-op care is standardized.

" . . . I think that centers contemplating a serious effort in this direction should at the minimum take advantage in one way or another of the knowledge that has been gained."

Stinson noted that the Stanford program has been visited continually by surgeons, researchers, nurses, administrators and others involved in starting up new programs.

"They've come here and learned details of the program, as well as obtaining a sense of the necessity for an orderly programattic approach to the enterprise," Stinson said, adding that he believes it is an unwritten obligation under the grant to help other medical centers set up transplant programs.

Dr. Norman Shumway and a colleague--Dr. Richard Lower now at the Medical College of Virginia--pioneered heart transplant research on animals starting in the 1950. After nearly two decades of research, Shumway performed the first adult human cardiac transplant in the United States. Shumway, who serves as chairman of the Department of Cardiovascular Surgery, remains active as a surgeon and researcher. His current interests include open heart surgery on infants, including premature infants. He is one of four faculty surgeons who regularly performs transplants. Stinson, who has been with the cardiac surgery team since Shumway's first transplant, now serves as principal investigator of the grant, provided by the National, Heart, Lung and Blood Institute of the NIH.

-more-

Many questions remain, including those related to immunosuppression, which "is not standardized insofar as it's based on this new agent (cyclosporine), and this new agent has toxicities such as impairment of kidney function mainly," Stinson said.

Even though cyclosporine has been successful at improving survival, little is known about how the fungal derivative works on the system. Extensive research, called pharmacokinetics, into the properties of the drug will continue, he said.

One of cyclosporine's difficulties is directly related to one of its strongest advantages. When rejection does occur--as it does at some time or another in 70 percent of all transplant patients--symptoms are usually not present. When other drugs were used, Stinson said, physical symptoms often served as a warning that rejection was underway.

The absence of such symptoms as fever or irregular heart beat means that more sophisticated monitoring techniques are needed to identify rejection. The most important tool, Stinson explained, is the biopsy. A thin wire is inserted into arterial tissue and a tiny clipper snips off a small bit of heart tissue which is sent to the laboratory and analyzed. The procedure, says Stinson, is safe but time consuming because of the necessity for frequent sampling. During the next five years, researchers will attempt to develop simpler procedures to monitor rejection, he said.

Also scheduled for extensive research in the lab, operating room and at bedside is the heart/lung transplant procedure. Eleven of 15 patients transplanted since March 1981 remain alive, and most have returned to busy productive lives, Stinson said. Three attempts at heart/lung transplantation a little more than a decade ago at other centers ended with failure, and Stinson credits the recent successful revival primarily to cyclosporine, which unlike other immunosuppresives permits rapid healing of the windpipe.

During the next five years, Stinson hopes to see about 30 isolated heart transplants annually. A major limiting factor, of course, is the scarcity of human donors, who must be brain dead but with beating hearts, whose family is willing to make their dead relative's heart available to help save someone else's life.

"There's never an end to trying to promote public education and cooperation in terms of organ donation for the forseeable future," said Stinson.

Stinson believes that while improvements will be made in all cardiovascular surgery, he strongly disagrees with those who would say that improved medications and lifestyles might eventually make heart transplantation obsolete.

"I don't think so," Stinson said, "unless you believe that immortality is to be achieved. People die because their organs fail."

HOSPITAL GIVES SECOND COMMUNITY SERVICE AWARD

STANFORD—

Kathryn E. Clair, Los Altos, was presented Stanford University Hospital's community service award for "perseverance and leadership" in developing a program providing housing for out-of-town patients and families.

Clair was cited in Dec. 21 ceremonies for "devotion to patients and families" in her efforts to lead the housing program of the Assistance League of Santa Clara County.

Conceived more than six years ago, the program first offered nearby rental apartments for patients and their families. Recently the university announced a $3.7 million grant to the Assistance League from the Hewlett Foundation for a 42-unit building providing low cost patient and family accommodations.

Clair is the second recipient of the hospital's community service award. The first, presented last year, recognized Charles and Rose Jones, whose East Palo mortuary has consistently provided free burials for premature infants who die at the hospital.

A brass plaque, which hangs prominently in the hospital, lists award recipients.

At the reception given by the Board of Directors and Administration of Stanford University Hospital, Stanford President Donald Kennedy praised the "unique partnership of two institutions (Stanford and the League) which have joined in the common goal of easing the needs of patients coming to the Medical Center for treatment. It is a partnership Stanford takes great pride in, and we are happy to be aligned with it."

Kennedy commended the "third partner in the venture," the William and Flora Hewlett Foundation of Menlo Park, which will finance construction of the new lodging for patients with their grant to the Assistance League, and cited the role of Roger Heyns, president of the Hewlett Foundation.

Sheldon King, executive vice president and director of the hospital, presented the award.

Clair and other Assistance League members had seen the need of out-of-town families for low-cost housing. "Many of us had personal experiences with family and friends with cancer. Being at the hospital day after day, we could see the desperate need they had to be the close to the hospital," she said.

Clair spearheaded the volunteers who undertook a study of housing needs for patients. In 1979, after extensive investigation, they leased two one-bedroom apartments in the Oak Creek complex near Stanford University Hospital. The league began offering nine-week rentals to families and patients at the rate of $10 a day and have since acquired five units for their program.

The units have been 100 percent occupied with a long waiting list. Lawrence G. Crowley, the university's vice president for medical affairs, called the league's operation extremely successful.

Clair calls the new building, to be located at the corner of Welch Road and Pasteur Drive, "a dream about to become a reality."

She joined the Assistance League, a national non-profit volunteer organization, in 1964 and is the chapter's only life member. She twice served as the organization's president and has been chairman of the League's HOME (Housing of Medical Emergencies) project since its beginning.

At the award ceremony, Clair announced that the League has made Jeanne Kennedy, Stanford University Hospital director of community relations, an honorary member of the organization, recognizing her work with the League for several years in planning the housing project and serving as liaison between Stanford and the League.

NEW HOSPITAL BOARD MEMBERS NAMED

STANFORD—

Three new members of the Stanford University Hospital Board of Directors were appointed by the general members of the Hospital corporation at their meeting Tuesday, Dec. 13.

The new board members are John Freidenrich, W. James Ware and Jack R. Wheatley. Each will serve a three-year term, beginning January 1, 1984.

Freidenrich is an attorney with the law firm of Ware, Fletcher and Freidenrich in Palo Alto. He received his undergraduate and law degrees from Stanford University (AB '59, LLB '63). He is a trustee of the Clumeck Foundation and a director of the Children's Health Council.

Ware, a graduate of Stanford University Law School (JD '72), is an attorney and partner in the law firm of Blase, Valentine and Klein in Palo Alto. He has been a member of the Stanford University Board of Trustees since February 1983.

Wheatley is chairman of the board of Wheatley Associates, a general contracting firm in Palo Alto. He is a graduate of the U.S. Military Academy at West Point. Wheatley was Palo Alto city councilman from 1967-71 and mayor of Palo Alto from 1970-71.

Members whose terms of office expire this year are William Ayer, Stanford University trustee, and David J. Stone of Palo Alto.

Reappointed to three-year terms are Geraldine F. Steinberg of Los Altos Hills and Dominick P. Purpura, M.D., dean of the Stanford University School of Medicine.

New on the board is David Korn, M.D., professor and chairman of pathology at Stanford, who replaces Dr. Kenneth L. Melmon as representative of the Faculty Practice Program.

Bylaws specify that 12 board members must be elected by the general members of the Hospital corporation. (The Hospital is a separate, University-owned subsidiary corporation in which the University trustees are also the general members of the Hospital corporation.)

Also, the board must include two general members of the Hospital corporation and seven other citizens who are not employees of Stanford University or the Hospital, of whom three must be Palo Alto residents and one a practicing community physician.

Members serve three-year terms. The board meets once every two months, and board committees meet at least quarterly.

Board members whose appointments continue are Walter L. Arons, M.D., Peter S. Bing, M.D., Lawrence G. Crowley, M.D., Conrad F. Gullixson, Donald Kennedy, Ph.D. (chair of the board), Sheldon S. King, William F. Massy, Ph.D., Linda Meier, Dean Morton, Nancy Munger and Frank H. Roberts.

STANFORD HOSPITAL OFFERS LIFELINE TO ELDERLY AND PHYSICALLY LIMITED PERSONS

STANFORD—

When Winifred Forse of Palo Alto was out during a recent wind storm, she fell and bruised her head. Luckily, she was with a friend who helped her to her feet again. But when she is at home, Forse needs a way to get in touch with a neighbor or friend in case a similar situation should arise.

That's where Lifeline, the new emergency response system based at Stanford University Hospital (SUH), comes in. Through the Palo Alto Senior Center, Forse got in touch with Lifeline chairman and Stanford University Medical Center Auxiliary member Joan Naber, who helped her become a subscriber to the system.

"Lifeline allows elderly and physically limited persoet the telephone unit.

SUH Emergency Department staff, on duty 24 hours a day, are available to respond to the signal sent by a home transmitter and will immediately call to determine what help is needed. If they are unable to make contact by telephone, they will call a neighbor or relative, who has agreed in advance to respond to emergency calls.

Though Forse says she didn't subscribe to the system because of any specific medical condition, she does suffer from emphysema, asthma and bronchitis, and her knees tend to give out on her. Having Lifeline gives her a way to contact help if any of these should become a problem.

"When I'm out, I'm always with people. It's just when I'm alone," Forse explains, that she feels the need for Lifeline. "It makes you feel like somebody's taking care of you."

Naber and other SUH volunteers began installing Lifeline units in the homes of elderly and physically limited persons late last month. Jeanne Kennedy, director of the SUH Department of Community Relations, initiated the project two years ago, and her office will coordinate the joint efforts of the SUMC Auxiliary, Little House in Menlo Park, the Senior Coordinating Council of Palo Alto (which operates the Palo Alto Senior Center), and the SUH Department of Emergency Services. The Palo Alto Medical Foundation and American Red Cross are also actively involved in the project.

The Auxiliary provided initial funding of $70,000 for the base communications system and the first 100 home telephone units. Approximately 30 units have already been assigned through the assistance of local senior community organizations. More units will become available during the next several months, Naber says.

Participants pay a small monthly fee for the service.

Although more home units are not expected to be available until after the first of the year, persons interested in the service may contact Naber at (415) 497-6906 for more information.

Community groups interested in helping fund the purchase of additional home units are encouraged to contact Sharon Beckham, Coordinator of Volunteer Services, at (415) 497-7424.

UNIVERSITY TRUSTEES APPROVE TWO NEW MAJOR RESEARCH PROGRAMS

STANFORD—

Stanford University Medical Center was given the go-ahead December 13 by the University's Board of Trustees to develop two new major programs in areas of basic and clinical research that promise dramatic changes for medicine in the future.

The two programs authorized for development by the trustees will focus on molecular and genetic medicine—to understand how the basic molecules of living things contribute to health and disease—and nuclear magnetic resonance—a technique whose potentially broad applications in medicine have only recently begun to be explored.

The trustees' action took the form of authorizing medical center officials to proceed with plans for buildings to house research in both these areas. Planning for both programs was initiated by Dr. Dominick Purpura, dean of the school of medicine, shortly after his arrival at Stanford in April, 1982.

The proposed Center for Molecular and Genetic Medicine would be a multistory building southwest of the main medical center, comprising 75,000 net square feet of laboratory and support space. The building is needed to accommodate up to 35 current and newly recruited faculty members involved in molecular and genetic research.

Construction of a 24,000 net square foot research animal facility is also included in the trustee-approved plans for developing the CMGM. (This proposed animal facility is distinct from a facility currently under construction at the medical center. The additional space is needed in order to complete replacement of existing animal facilities and to accommodate new demand that would be generated by CMGM programs, according to medical center officials.)

The estimated cost of the project is $45 to $56 million, with $29 to $36 million required for construction of the CMGM building, $13 to $17 million needed to build the animal facility, and approximately $3 million required for moving existing temporary buildings from the site and constructing new space to house those programs currently located on the site.

Medical center officials project that $45 million could be raised from public and private sources to support costs of the CMGM building, but that some costs of the animal facility might be handled through debt financing.

According to a tentative schedule for the project, design could be completed and construction started in the fall of 1985, with construction completed by the fall of 1987.

According to Purpura, the new center and the academic program it represents, are of the highest priority for Stanford Medical Center. "The purpose of an academic program in molecular and genetic medicine is to provide the scientific and intellectual framework necessary to speed the pace of anticipated research advances and their translation into revolutionary methods of diagnosis and therapy of human disease," Purpura said.

12-14-83

-more-

Stanford medical center faculty members have played a major role in developing the "new genetics" that has emerged in the last 20 years, according to Purpura. During the coming 20 years, molecular and genetic studies will continue to form a major thrust of medical school research, he said.

The CMGM program builds on excellence in the departments of biochemistry, genetics and medicine, as well as helping to rebuild the department of physiology, Purpura noted. The new building will provide laboratory space for 15 to 20 new faculty members who will be recruited, as well as helping alleviate the severe shortage of research space available to current faculty members at the medical center.

Research will include efforts to understand structure and function of the genetic material at the molecular level, as well as basic investigations in areas of immunology, developmental and cellular biology. A special emphasis will be placed on using molecular, biochemical and cellular genetics approaches to studying a variety of diseases and disorders, including cancer.

A committee of eight faculty members conducted the initial planning for the molecular and genetic medicine program and center, according to Purpura. The CMGM is currently administered by four faculty members appointed by the dean of Stanford's school of medicine.

The Nuclear Magnetic Resonance Center is to provide 11,000 net square feet of space for basic and clinical research activities devoted to NMR. The building may also be located southwest of the medical center, and will house up to five NMR instruments, as well as facilities for patient-related research, and other laboratory and office space.

The building will consolidate space for several Stanford faculty members already committed to NMR research but currently working in various departments throughout the medical center and the rest of the university.

The NMR research facility should take approximately one year to design and one year to construct, according to medical center officials. The cost for building construction and purchase of three new NMR instruments is estimated at approximately $9.5 million. The money will be provided by a combination of private gifts, federal grants and debt financing.

Medical School Dean Purpura identified the NMR Center as complementary to the Molecular and Genetic Medicine Center and also of highest priority to the school's academic and research programs.

Although the NMR phenomenon has been understood for almost 40 years, he said, its revolutionary potential in medicine has only become clear in the last decade. "Establishment of the NMR Center would ensure Stanford's continuing leadership in the rapidly expanding field of basic and clinical applications of NMR," Purpura said.

Nuclear magnetic resonance refers to a general phenomenon in which different types of atoms and molecules can be distinguished from one another after exposure to a strong magnetic field. In clinical use, this phenomenon can be exploited to give information about body chemistry and physiology.

NMR imaging—making pictures of the body using the technique—is thought to be one of the most important diagnostic discoveries since the x-ray was introduced. Research applications of NMR imaging are likely to be vast. Other uses of NMR in medicine have equally great potential. "Many of the most significant developments will require the invention and development of new applications, methods and instrumentation. A Center pooling the institution's intellectual and technical resources to provide a critical mass of expertise is the most likely environment to foster creative development," Purpura said.

The NMR Center would be directed by three faculty members appointed by the medical school dean.

Funding for both programs approved by the trustees will be sought as part of a major fundraising program, currently in the planning stages, in behalf of the Medical Center.

YALE RADIOTHERAPIST JOINS STANFORD FACULTY

STANFORD—

Dr. Daniel Kapp, a Yale radiotherapist, has been appointed to the faculty of Stanford University School of Medicine, effective Jan. 1, 1984.

Kapp will serve as associate professor of radiology, a tenured appointment in the division of radiation therapy, where he will co-direct clinical activities of the hyperthermia program.

This treatment technique, most commonly used as an adjunct to radiation and/or drugs in cancer therapy, involves inducing moderate temperature elevations in malignant tissues in order to sensitize tumors to standard forms of therapy. Heating may be accomplished by employing microwave, ultrasound, or radiofrequency devices.

Dr. Malcolm Bagshaw, professor and chairman of radiology and director of radiation therapy, said Kapp's appointment reflects Stanford's long-term commitment to investigating hyperthermia for the treatment of those types of tumors which are suitable targets.

At Yale, Kapp has been chief of the gynecologic radiation therapy service, and in addition to other clinical duties has focused his laboratory research on both *in vivo* and *in vitro* studies of interactions of hyperthermia, radiation therapy, and a variety of either radio- or thermal-sensitizing drugs.

Kapp is expected to continue these studies at Stanford, as well as participate in gynecologic and other clinical coverage. He will share teaching responsibilities in the division's programs offered to both medical students and housestaff, and be responsible for integrating hyperthermia subject matter into the program.

A native of New York, Kapp received both his Ph.D. and his M.D. at Stanford University. He has served since 1976 on the therapeutic radiology faculty at Yale University School of Medicine.

Kapp's new appointment was approved by the Stanford University Board of Trustees last June.

NEW CLINIC OPENS FOR BACK PAIN SUFFERERS

STANFORD—

A new spinal disease and trauma clinic is scheduled to open at Stanford University Medical Center Jan. 1, 1984.

The clinic, said Dr. Vicki Kalen, assistant professor of surgery (orthopedics), will for the first time focus the division's energies on back patients—"something we haven't previously done."

Kalen, who joined the Stanford faculty in July 1983 and who will serve as chief of the new service, explained that the orthopedics clinics so far have dealt primarily with problems of the extremities.

She now expects to see patients with a whole gamut of spinal diseases and injuries, including minor to major back injuries, disc problems, aging problems affecting the spine, fractures, congenital spinal deformities, and spinal infections.

"About 75 percent of the population experience back problems at some time," she said, "and certainly the first consultation should be with the family physician, not us." The clinic, she said, will be equipped to handle more serious problems that require further consultation.

Treatments offered will vary widely according to patient need, but may include surgical approaches as well as the use of chymopapain, an enzyme used successfully in many patients to dissolve slipped discs and avoid surgery.

The new clinic will be located in the Edwards Building, orthopedics division. Other physicians are Dr. Donald Nagel, professor of surgery (orthopedics), and Dr. Moylon Kehoe, clinical instructor of orthopedics. A member of the physical therapy department will also join the group.

The phone number of the clinic will be (415) 497-5341.

HOSPITAL COMPLETES EMPLOYEE INVESTIGATION

STANFORD—

Stanford University Hospital (SUH) announced completion Monday (Dec. 12) of an internal investigation stemming from the arrest of six employeees on various drug related charges.

Carole Price, associate administrator, said four employees have been discharged, another worker was suspended for 10 days, while the sixth employee was reinstated with back pay. The workers were informed of the personnel action in registered letters sent by SUH on Tuesday (Dec. 6), Price said.

All six employees had been suspended Nov. 18—the day of their arrests by Palo Alto Police—pending the hospital's investigation of the matter "from an employment context," Price said.

Reinstated was Randy Creamier, 22, Mountain View, an operating room orderly. "Based on the information supplied in conjunction with the Palo Alto Police Department's five month investigation prior to the arrests, it was determined there was insufficient evidence to warrant discipline of Mr. Creamier by the hospital," Price said.

David Cannon, 34, a pharmacy technician, was reinstated to his job after a 10-day suspension without pay, Price said.

Those terminated were another pharmacy technician, Kirk Williams, 31, Redwood City; Rommel Day, 27, Palo Alto, a food service worker; Craig Julien, 21, a linen assistant, East Palo Alto; and Mike Robinson, 26, a mail room clerk, San Carlos.

Court charges against Creamier, Day, Julien and Robinson involved the alleged sale or alleged offer for sale of cocaine. Charges against Williams and Cannon involved the alleged sale of controlled substances (including codeine, Talwin and Valium) from the hospital pharmacy.

Charges following the arrest of the six employees were pending in Palo Alto Municipal or Santa Clara County Superior courts.

Meanwhile, the hospital, at the request of the pharmacy department has initiated an internal audit of controlled substance procedures and is conducting further review in cooperation with regulatory agencies, said Donald Utt. associate administrator.

MALAYSIAN FOUNDATION GIVES TO CANCER RESEARCH

STANFORD—

The Kwok Foundation of Malaysia has given $1 million to Stanford's division of oncology, to support cancer research and training programs at the School of Medicine.

Foundation chairman Philip Kwok said the gift, presented to President Donald Kennedy Dec. 5, was intended to facilitate the training of Malaysian physicians in cancer research here, and to encourage the development of a new center for cancer research and patient care at Stanford.

A previous Kwok Foundation gift has helped support the training of Malaysian doctors in other divisions of the department of medicine. The Foundation's seven-member board decided to extend the most recent gift to show gratitude for treatment received here by a Kwok family member who had suffered from terminal cancer.

"Primarily we plan to use the money to strengthen our program for postdoctoral trainees, which often involves an extended training period," said Dr. Saul Rosenberg, professor of medicine and radiology, and chief of oncology.

"We will of course welcome any qualified Malaysian physician to the program," he added, noting that already the gift has helped to initiate discussion towards further professional exchange between the two countries.

Also representing the Foundation last Monday was Dr. S.M.A. Alhady, a member of the board.

The Kwok Foundation has supported advanced training in the arts and humanities in both Oxford and Cambridge, England. Stanford is the first recipient of Kwok donations to the biomedical community, Rosenberg said.

COMPUTER LAB AT STANFORD

STANFORD—

An interactive computer course for first-time users with no computer background will be held on the Stanford campus for seven consecutive Wednesday evenings, beginning on Jan. 11, 1984. Sponsored by the Continuing Education program of the Stanford Alumni Association, the course will be held from 8-11 p.m.

The course will emphasize "hands-on" experience using the spreadsheet/database application for the IBM Personal Computer, LOTUS 1-2-3. Six sessions will present an overview of this computer model's capabilities and features such as the spreadsheet, graphics, and database usage. The seventh session will examine the state-of-the-art hardware and software display at Forsythe Hall's computer center.

PC LAB is limited to 16 participants. Tuition for the course is $300.

For course registration information call Paqui Nelson, associate director for Continuing Education, Bowman Alumni House, Stanford University, 497-2021.

ROBINSON NAMED PERSONNEL DIRECTOR

STANFORD—

Daniel J. Robinson has been named director of personnel management at Stanford University Hospital.

Robinson has been acting director of the department since March. His appointment, effective Dec. 7, was announced by Carole Price, associate director of the hospital, after a formal search process.

"Dan is highly respected within the organization and has long been an active proponent of strong fiscal management and the recognition of staff contributions," said Price. He was selected following a formal search process.

Robinson joined the employee relations section of the hospital in March 1979. He became manager of employee/labor relations, and then in 1981 assistant director.

Previously he was labor relations administrator with the Matson Navigation Company and also with the Pacific Maritime Association, both in San Francisco. He received a bachelor's degree from the University of San Francisco in industrial psychology.

Robinson has overall responsibility for planning and budgeting the personnel management department which includes employee relations, labor relations, employment/recruitment, wage and salary administration, pension and benefits, and personnel health services.

STANFORD OPENS ANIMAL FACILITIES TO LIMITED PUBLIC VISITS

STANFORD—

Limited public visits to Stanford University's laboratory animal facilities are being offered under a new public access policy, Associate Dean for Administration David Mendelow announced Monday (Dec. 12).

"In recognition of the university's continuing and increasing obligation to inform the public about the important role animals play in biomedical research, and to reinforce its commitment to openeness and public accountability, representatives of recognized groups in animal welfare and accredited representatives of news organizations may arrange to visit the facilities," Mendelow said in a statement.

Occasional public visits to various campus locations where animals are housed had been available in the past and animal facilities have always been open to government agencies regulating animal welfare and to academic accrediting groups.

Mendelow said the essential change in policies involves the adoption of specific guidelines, "and a renewed commitment that visits—when they can be arranged without interference to ongoing research or the welfare of indvidual animals—are an important obligation to the public which feels a genuine concern that animals being housed for important scientific research are being cared for appropriately and humanely," Mendelow said.

Under the guidelines, "representatives of recognized groups involved in animal welfare" may request in writing that a visit be scheduled. In order to protect animals from communicable disease and the agitation caused by the presence of strangers, no more than two groups may be scheduled each month, and group size will be limited to eight persons, said Carolyn Reed, acting director of the Department of Laboratory Animal Medicine (DLAM).

The restrictions, Reed said, are also intended "to protect the public from potential hazards and the potential spread of disease from room to room. Staff who care for the animals must be continuously monitored for the state of their personal health."

Mendelow said he believes "there is no question that the topic of animal research is one currently generating a great deal of public concern. We feel it is important for an institution involved in this lifesaving research to maintain openness and to become involved in the issues.

12-9-83 -more-

"We are proud of our research and the role played by animals in extending important human knowledge," he added. Dean Dominick Purpura has said that more than 90 percent of all medical knowledge in the last century has been directly dependent on studies involving laboratory animals.

Mendelow said the public would be able to see various animals currently housed in a variety of facilities at the medical center and other locations on campus. Next fall, visits are expected to focus on Stanford's state-of-the-art $12 million Research Animal Facility, which will enable most laboratory animals to be moved into the single housing complex.

Between 15 and 25 species of animals are used in research at any given time, depending on needs. About 95 percent of the animal population are rats and mice, but DLAM facilities are equipped to handle most animals, including a farm area for larger primates, and several kennel areas for dogs, which are used primarily in heart research.

Ordinarily, said Mendelow, visits could not include entry to sterile research areas, because of the potential of disease transmission. All visits would be subject to the final approval of the DLAM director, he said.

Members of animal welfare groups wishing to visit the facilities should contact the Director, Division of Laboratory Animal Medicine, Quad 7 Building 960T, Stanford University, Stanford, CA 94305.

News media representatives wishing tours should contact the Medical Center News Bureau, Suite 301, 750 Welch Road, Palo Alto, CA 94304, (415) 497-6911.

VOLUNTEERS NEEDED TO COMPARE BENEFITS OF HIGH AND LOW LEVEL EXERCISE

STANFORD—

Currently sedentary 40- to 60-year-old male volunteers are being recruited to begin the New Year—with or without a resolution—by participating in a Stanford University Medical Center study comparing the health benefits of low and high level exercise.

"Especially in sedentary people, low level exercise will produce the same training effects as high level exercise—it just takes a little longer," said Dr. Robert DeBusk, director of the Stanford Cardiac Rehabilitation Program.

To confirm this belief, DeBusk and his researchers will involve three randomly assigned groups of volunteers in the three-month study, which begins Jan. 16. One group will carry out their usual activities (control group); another will carry out low level exercise training such as brisk walking; and the third group will perform high level exercise training such as jogging.

Portable heart rate monitors will be used to help volunteers maintain the appropriate intensity of exercise, and individualized instruction will be given concerning the amount and duration of exercise training.

After initial telephone screening, volunteers will undergo a preliminary evaluation including medical history, physical examination, treadmill exercise test and measurement of blood fats. Participants will repeat the treadmill test at six and 12 weeks and will be asked to record their food intake and physical activity. They will also wear a heart-rate recorder at specified times during the study.

Participants must be free of cardiovascular disease and cannot have participated in any sort of regular exercise program for at least three months prior to the study.

DeBusk said one potential benefit of participation in the project is thorough screening for latent (unrecognized) cardiovascular disease. In addition, participants will have the opportunity to potentially increase their cardiovascular fitness.

On completing the study, which is funded by the Pepsico Foundation, participants will be given an individualized "prescription" for ideal long-term exercise conditioning.

For more information, call the cardiac rehabilitation program at 497-6461 during regular business hours and ask for the "coordinator of the high/low study."

STANFORD'S NURSING SERVICE ENCOURAGES AUTONOMY, EDUCATION, RESEARCH, AND CLINICAL EXCELLENCE

STANFORD—

Walking through the corridors at Stanford University Medical Center, it's sometimes difficult to distinguish the nurses from the rest of the staff. The traditional white caps, matronly dresses, support hose, and orthopedic shoes that used to make up the stereotypical image of a nurse are long gone. No longer are they thought of as "old maids," tyrannical in their spinsterhood, or young "sexpots" waiting for their catch from the medical pool.

They may be discernible only by their name tags, but Stanford's nurses stand out—known among the health care community as assertive, confident men and women skilled in their profession and dedicated to service for the sick.

And Stanford stands out among the nation's hospitals—known as the ideal place for nursing. Nurses here are encouraged to be involved with education, research, and global professional issues. They're given responsibility, autonomy, flexibility, and a significant say in patient care. They're among the highest paid nurses in the country. They're staffed according to the patients' needs, dependent on the severity of the illness. Rather than rely on temporary nurses from agencies to fill in for staff nurses, they have a pool of relief nurses familiar with the hospital, the staff, and many patients. They have a professional union that represents only them. In everything they do, nurses say, the goal is to improve patient care.

"The main focus of nursing has always been bedside care of the patient," says Ellie Hedenkamp, a cardiology nurse specialist on the pediatrics unit. "But the peripheral issues—the education, the technology, the research—are what's changing nursing."

"Nursing here sets a precedent for all nursing in the country," observes Lois Welches, an associate director of nursing. "We have a group of overachievers like I've never seen before. There's a major commitment to quality health care. Because of that, the nurses can't stand to keep things at the status quo. They're constantly coming up with intelligent, innovative, and creative ideas to improve patient care."

It's no accident that the 1,200 nurses here stand out from the nationwide force of nearly one-and-one-half million. Shortly after he became director of the nursing service nearly six years ago, Duane Walker stepped up recruitment of nurses with diverse education and experience. Nearly half the nurses here have bachelor's degrees in nursing, while about 15 percent have master's or higher degrees.

2-2-2 It seems once they experience working at Stanford, they're reluctant to leave. Even at the height of the nursing shortage just a few years ago, when many nurses were switching jobs like musical chairs depending on which institution played a better tune, the turnover rate here was a comparative nationwide low of 37 percent. Now, it's less than one percent, with as many as 100 names on the waiting list at times.

"As recently as five years ago, I would ask each group of new nurses why they came to Stanford. At least 80 percent said they came because of a specific doctor's work," says Walker. "Now when I ask the same question, about 70 percent say they came because they've heard about the nursing service here."

One unique aspect at Stanford is the nursing research program, so successful that it recently was awarded a $600,000 grant by the Department of Health and Human Services, the first ever given to a hospital-based nursing department.

"Nurses look at research as problem solving," Walker explains. "When you get into that mode of thinking, you increase the quality of care."

Established in 1979, the research program's objective is to "help meet public and professional demands for quality cost-effective patient care by developing the research skills of nurse-clinicians and encouraging the integration of nursing research activities as a part of nursing practice."

Research projects range from specific clinical problems, such as one that determined the most effective and least costly treatment for bed sores, or one that determined which method of collecting breast milk for hospitalized infants remained the most free of bacteria and viral infections, to broader topics, such as the patient satisfaction study, or the survey of dietary problems as perceived by nurses and dietitians. There's no reward system for participation in research, Walker notes, just a lot of encouragement and individual ambition.

"Nurses at medical centers usually have the advantage of being connected with a nursing school where they have access to faculty and research-oriented facilities," Welches, who heads up the research program, points out. "The amazing thing about Stanford is that even with no nursing school, the nurses have been able to do as much and more than the others."

Another component is education—of nurses and patients by nurses. The entire profession is pushing for a higher educational entry level into nursing, specifically a minimum of a bachelor's degree. The reason, Welches explains, is that with more education, nurses are able to be more critical of their work, thus improving it. "Education is the key to upgrading the image of nursing," Walker adds.

Stanford nurses have developed teaching programs among themselves as well. Many, such as the graduate program in cardiology and the proposed operating room management program, are nationally one-of-a-kind.

"Five years ago, doctors' classes attracted nurses. Now, nurses want to be taught by nurses," Hedenkamp says.

Possibly completely unacceptable in many institutions, nurses also participate in the education of physicians. Aside from the classes nurses teach in the medical school, nurses help train new interns and residents as part of the young physicians' education. Nurses and physicians can volunteer to spend a 24-hour work period with one another in order to gain an understanding and appreciation of what each encounters during a typical day's work. This new program is an extension of physician/nurse committees that exist on just about every unit, giving members a forum to discuss patient care problems and come up with solutions.

-more-

"When they were first established nearly two years ago there was a lot of venting of frustrations," alker says. "But eventually they got tired of talking about problems and started planning. That was what we were gearing towards."

Perhaps the most important part of education, however, is that of patients and community members. For many patients, the nurse is the only constant, explains Patty Tharp, who works in the cardiology intensive care unit. "Many times the physician only comes in to check the patient's condition for a few minutes each day," she says. "The nurse is the one who provides the round-the-clock care." Often the patient advocate, the nurse is the one to answer questions about procedures, medications, and operations.

In addition to education nurses provide to patients within the hospital, they participate in community programs geared for education, such as health fairs.

"This is all part of making nursing more visible and improving its image," Walker says.

"Medicine is disease-oriented, and doctors are disease treaters, whereas nurses are health care-oriented," Hedenkamp notes. "Nurses look at patients in their total health care status. We do that in a much wider scope now, with outreach education programs, health maintenance, and disease prevention programs.

"The nurse's goal is not to cure—that's unrealistic—but rather to put patients in the best possible physical condition and help them and their families deal with that condition," she continues. "If you feel you've made it easier for them to handle whatever their specific situation is, you feel you've accomplished omething."

As such, nurses feel they are invaluable, yet disparate, members of the health care team. "Nurses have been struggling so long for identity," Walker says. "We've been accused of trying to take over the medical domain, but I don't see that as our goal at all. Nurses are simply saying to physicians that we want you to recognize that we are vital members of the health care team. We want to be considered not as the handmaidens, but respected for the knowledge base we have."

And for the most part, nurses feel the physicians here do just that. "There are two schools of thought. Some of the old-time physicians really think the nurse is a handmaiden, that she doesn't need to know anything except what the physician tells her," Hedenkamp says. "In general, though, the relationship between physicians and nurses is excellent. Nurses are being asked to make increasingly more complex decisions, and to be more responsible for their judgment and management of patient care. Most physicians act very collegial and respect nurses for the skills and knowledge they contribute.

"Stanford is an excellent place to work," she continues. "Patients get a combination of first-rate technical care and a lot of caring. It's a very human-oriented place."

"The nurses here don't look at their job as just a job," Tharp adds. "They put in the extra time and effort, whether it's staying after the shift is over to write a nursing care plan, or consulting with others abut the patients' care. Nurses here are intereted in their jobs, they're dedicated, and they genuinely want to provide the best possible care to their patients."

FOR IMMEDIATE RELEASE

TRANSPLANT SURGEON CALLS FOR MORE FLEXIBLE DONOR RELEASE POLICY

A Santa Clara County Coroner's policy which prohibits harvesting of donor organs from homicide victims should be changed to provide body parts to desperately ill recipients when they are not clearly needed as medical evidence, a Stanford Medical Center cardiovascular surgeon said Thursday (Dec. 1).

Philip E. Oyer, associate professor of cardiovascular surgery and a senior member of Stanford's heart transplant team, said he believed a decision this week by the Santa Clara County Coroner's Office refusing transplantation of a heart and both kidneys from a man who had been fatally shot in the head was unnecessary.

"We have one of our own heart patients and two kidney patients from other hospitals who will now have to wait longer for the organs they need for survival," Oyer said. "If there had been anything physically wrong with the heart related to the patient's injuries we couldn't have used it for transplantation in any case," Oyer said.

John Fait, administrative officer with the chief medical examiner of Santa Clara County, said he had denied Stanford's heart transplant team permission to harvest the heart from Orlando Taylor, 18, who was declared brain dead at Stanford University Hospital. Menlo Park Police said he had been shot in the head while driving his car through East Palo Alto last weekend.

Oyer said the coroner's office had declined to allow the heart to be transplanted by Stanford and the kidneys by the UC San Francisco Medical Center after the family had given permission and after several requests for the coroner to reconsider his decision. By Tuesday night, life support systems were withdrawn from Taylor and his body was released to the coroner for autopsy.

Fait said Thursday that a gunshot wound to the head was determined as the cause of death.

Fait said his office routinely refuses organ donations homicide victims in order to "protect the physical evidence to the best of our ability."

Dec. 1, 1983 -more-

Fait said the homicide refusal policy was based on a meeting between Stanford physicians, administrators and the coroners office in 1969. Oyer said he understood there was such a meeting, "but that was before the concept of brain death had been fully established. The policy is clearly outdated and needs to be changed."

Oyer said the transplant team has worked effectively with medical examiners in many jurisdictions, including Los Angeles County, where bodies are released immediately to the coroner after the organs are harvested and full reports regarding the physical condition of the organs taken for transplant are supplied promptly to the coroner's office.

"This most recent case is particularly illustrative of the need for a change of policy," Oyer said, "because it was apparent that the heart and kidneys were healthy and had not been injured in the trauma which resulted in death."

Current state law gives county coroners wide latitude in allowing transplantation following death through its authority to demand bodies for autopsy. Oyer said he believes that a more enlightened policy "based on current medical knowledge and concepts of brain death" is needed. He said he is unsure whether the law should be changed to facilitate transplants.

Fait said his office has been cooperative with Stanford in the past and has authorized seven bodies for transplantation, none homicides, in the past 13 weeks.

VOLUNTEERS NEEDED FOR STUDY OF ANOREXIA, AN UNUSUAL DIETARY DISORDER

STANFORD—

Stanford University Medical Center researchers are looking for 40 volunteers to participate in a study of anorexia nervosa, a disorder in which young women diet obsessively, sometimes to the point of starvation.

The researchers plan to study the relationship between anorexia nervosa and body levels of zinc, an essential mineral.

"There are many similarities between the clinical picture of zinc deficiency and anorexia nervosa," explained Dr. Rebecca Katz, who is conducting the study. "Both conditions are characterized by weight loss, growth retardation, loss of appetite, decreased taste acuity, lack of menstrual periods in females, delayed sexual development, mood changes, and hair and skin abnormalities."

Volunteers must be anorexic individuals under 21, said Katz. Those accepted into the study will undergo a medical history and physical examination, which includes taking blood and urine samples. Volunteers will also be asked to keep a record of everything they eat for three days, Katz added.

The study is being conducted at Children's Hospital at Stanford through Stanford medical school's division of adolescent medicine. Individuals who would like to volunteer may call Dr. Katz at (415) 327-4800, extension 538, weekdays between 8 am and 5 pm.

VETERANS' GROUP ENDOWS PERMANENT SPINAL INJURY PROFESSORSHIP

STANFORD—

A permanent professorship focusing on spinal cord injuries is scheduled to be inaugurated at Stanford University Medical Center at a ceremony on Friday (Jan. 27).

Paul Cheremeta, president of the Paralyzed Veterans of America (PVA), is scheduled to present a check for $150,000 to Stanford to initiate the endowed chair, approved by the university Board of Trustees last September. The money is the first installment on a pledge expected to bring a PVA endowment total to $1 million within this decade.

The significance of the Paralyzed Veterans of America Professorship of Spinal Cord Injury Medicine, said Ed Jasper, PVA national treasurer, "is our organization's hope that the American Medical Association will recognize spinal cord injury medicine as a specialty."

Spinal cord injury research and treatment, Jasper said, is too often scattered among other specialities, including orthopedics, surgery and neurology.

In 1980, PVA contributed $260,000 to fund a term professorship which will run until August 1985.

Jasper said Stanford "had foresight in establishing it as a term chair until the organization was able to endow it permanently." The term chair was and remains the only temporary chair at Stanford.

Lawrence G. Crowley, vice president for medical affairs, said:

"The Paralyzed Veterans of America were extremely generous four years ago when they established a term professorship. The most recent pledge will perpetuate and enhance the effort we are making in research on behalf of the 10,000 persons each year who sever their spinal cords."

The term chair is held by Inder Perkash, associate professor of sugery and chief of the Spinal Cord Injury Service at the Palo Alto Veterans Administration Medical Center.

Crowley said the principal and some of the earnings from the term chair will be used to fund the permanent professorship. Other portions of the earnings have been used to support the teaching, research and clinical activities of the chair holder.

Endowed chairs are intended to honor both the recipient and the award's donor or namesake. Sometimes the money is used to supplement or provide salaries for eminent faculty members, while other times the money is used to support research activities of these faculty members.

The PVA is one of 14 veteran's organizations chartered by Congress. The national group claims a total of 11,000 members.

NURSE'S UNION AND HOSPITAL BEGIN CONTRACT TALKS

STANFORD—

Representatives of Stanford University Hospital and the union representing the institution's 1,250 registered nurses have announced that collective bargaining began this month this month for a new agreement.

In a statement issued last Wednesday (Jan. 25), the hospital and the union, The Committee for the Recognition of Nursing Achievement (CRONA), said the teams "have agreed to issue joint press statements as necessary during the negotiatons."

The present two-year contract expires Feb. 28.

The CRONA team is composed of chief negotiator and former CRONA President, Hedy Dumpel; the current CRONA president, Myra Lang; and other registered nurses, Sue Elders, Alice Serbein, Joanne Muir, and Jean Krsnak.

The hospital's chief negotiator is Priscilla Wheeler, staff counsel and the university's chief labor attorney. Other members of the team include Daniel Robinson, SUH director of personnel management; Joyce Miller, associate director of nursing; Judy Lanigan, assistant director of nursing; Laurie Gunderson, clinical nursing coordinator; and Susan deJongh-Kearl, university associate staff counsel.

PHYSICIAN AWARD TO HONOR PATIENT CARE ESTABLISHED

STANFORD—

An award to recognize the importance of good patient care by physicians at Stanford University Hospital (SUH) has been established in memory of Dr. Alwin C. Rambar, a long-time Chicago pediatrician.

The Alwin C. Rambar Award for Excellence, was announced Thursday (Jan. 25) by Lawrence G. Crowley, vice president for medical affairs.

The award is to be presented annually at medical school commencement to a physician on the SUH staff, Crowley said. The first recipient is expected to be announced this June.

Criteria include compassion in dealing with patients and families, effectiveness in working with non-physician members of the health care team on behalf of patients, and excellence in treatment. Recipients are to be selected by an advisory group to the vice president for medical affairs, representing the medical faculty, voluntary faculty (community physicians), house staff, nursing staff and patient relations staff.

A permanent plaque bearing the names of award holders will be displayed in the hospital. A cash award is also to be given.

The award was established at Stanford by members of the Rambar family, including several living in the mid-Peninsula area.

NEW ASSISTANT DEAN TO FOCUS ON MINORITY AFFAIRS

STANFORD—

Dr. Roger Peeks, a former medical student, intern and resident at the Stanford University School of Medicine, has been appointed assistant dean for student affairs, announced Dr. John Steward, associate dean.

Peeks, who is in private practice in Oakland, will work here one day each week, dividing time between the office of admissions and the office of student affairs. Along with general counseling responsibilities, his duties will include:

* recruiting and counseling black applicants, including visits to undergraduate campuses and programs, interviewing applicants, and serving in an advisory capacity to the director of admissions;

* serving as a liaison between the medical school and various offices and organizations, both local and national, particularly in relation to minority affairs;

* assisting in the planning and acquiring of funds for special programs to enrich the experiences of Stanford's minority medical students;

* and helping with academic advising and personal counseling of medical students.

Peeks will concurrently hold the title of clinical assistant professor of medicine, a position he held formerly at Stanford.

Peeks served as acting assistant dean while he was a physician specialist in Stanford's department of medicine during the 1981-82 year. In addition, he was the assistant director of admissions at the medical school. During that time his clinical responsibilities were based at the Palo Alto Veterans Administration Hospital, where he also taught and supervised medical residents, interns, medical students and nurse practitioners. He was a freshman premedical advisor at Stanford from 1979-82.

After Peeks left, Dr. Fernando Mendoza was appointed assistant dean. Now, the two will work together to expand activities providing special support for minority students.

Steward emphasized Peeks' age—he received his M.D. in 1978. "His own medical student experience is recent enough for him to identify closely with our students, and they with him."

NEW INTERFERON DRUG UNDER STUDY TO TREAT HEPATITIS B

STANFORD—

Stanford University Medical Center scientists are ready to begin treating chronic hepatitis B patients with a new genetically engineered interferon drug that they think may be more effective than other medication in controlling the disease.

The drug, called beta-ser fibroblast interferon, is one of only a few interferons manufactured by recombinant DNA techniques to be used in treating the incurable liver ailment.

The research team, led by infectious disease specialist Dr. Thomas Merigan, believes the drug may be given in large doses to decrease the amount of the hepatitis B virus in the bloodstream on a long-term basis. Previously tested interferons did lower the amount of virus in the bloodstream, but only during the time period in which the patient was being administered the drug, Merigan said. Genetic engineering has made the new drug more stable, he continued, which hopefully will lead to long-lasting loss of the virus.

Hepatitis B is a unique virus that causes infection of the liver, Merigan said. There is no cure for the disease, which afflicts more than 100 million people worldwide. The virus can be found in all of the body's secretions and fluids, and can be spread by intimate contact or by contaminated medical or dental instruments. Population groups considered at high risk include hemodialysis patients, medical or dental workers, gay males, and users of illicit intravenously-administered drugs.

Various therapies for the disease have been undergoing clinical testing at Stanford for about 10 years. Interferon, a protein the body produces naturally in minute amounts that increases the defense system against malignant cells and viruses, was first incorporated in hepatitis B treatments in 1974. Initially hailed as the "cure-all wonder drug" by scientists in 1978, only with the development of recombinant DNA techniques in 1980 did interferon become available in quantities large enough to be considered practical and affordable.

1/24/84

-more-

Patients interested in volunteering to participate in the clinical testing of the new drug must be between 21 and 65 years of age. They must be carriers of the virus for at least 12 months. All participants must have a liver biopsy that must show chronic hepatitis B.

Those accepted into the study will receive daily intravenous injections of different doses of interferon for one week of each month for four months.

The researchers are also seeking hepatitis B patients to participate in an ongoing clinical trial of a drug called adenine arabinoside monophosphate (Ara-AMP). Scientists have been testing this drug since 1981 to see how effectively it causes a permanent decrease of the virus in the bloodstream, improves the liver disease, and lessens the ability of patients to infect others, according to Dr. Gabriel Garcia of the gastroenterology division.

To qualify to participate in the trial, patients must be between 21 and 60 years old. They must be carriers of the hepatitis B virus for at least 12 months, and a liver biopsy must show existence of the virus. Scientists must also be able to determine how much virus is in the bloodstream through blood tests.

Because both drugs under study are experimental, some side effects may be encountered, Garcia said. These may range from nausea and vomiting to pain in the feet and lower legs, rarely accompanied by weakness of muscles. All side effects, Garcia pointed out, tend to disappear after treatment is stopped.

Participants are requested to commit themselves to the study for two years. They will receive treatment for five months, and will be under observation for the remaining 19 months.

To inquire about either study, call Stanford's hepatitis research clinic at 415-497-6231.

BLOOD DONATIONS SHOW A SLIGHT FALL, DUE TO UNREALISTIC FEAR ABOUT AIDS

STANFORD—

The AIDS epidemic has claimed another victim: blood donations are down nationwide. Stanford University's Blood Center is no exception, with a 3 to 4 percent decrease in donations over the past six months.

One problem may be that people have the mistaken impression that *giving* blood can expose them to AIDS, said Rhoda Burns, recruitment supervisor at Stanford University Blood Center. It's an error that Burns is eager to help clear up.

"There is absolutely no AIDS risk associated with donating blood," Burns contended. "Not only is all equipment sterilized, but each syringe is used only once and then discarded," she added.

The barrage of publicity given to AIDS (acquired immune deficiency syndrome) has distorted the public's idea about blood donations, according to Burns. Only a small number of the thousands of reported AIDS cases nationwide are suspected of being caused by blood transfusions. Yet both blood transfusion and blood donation have taken a bad rap, said Burns.

"It's guilt by association," she observed. "When Mustangs got recalled, overall Ford sales went down. Now that people are worried about a very small hazard associated with receiving blood, the fear has spread, unjustifiably, to blood donation as well."

AIDS fears have had an impact on the Blood Center in other ways, noted Burns. One of these is an increase in "autologous donation." This is a previously little-used donation program in which people who are planning to have an operation may, through their physician, arrange to give their own blood in advance to be used at the time of surgery if necessary.

A second program called "directed donation" is receiving more attention, Burns said. Stanford Blood Center is one of only a few blood banks in the country with such a program.

1-23-84

-more-

In directed donation, a patient may ask specific individuals—usually family members or friends—to donate blood in their behalf. The blood is then earmarked for that patient, as long as it is compatible with the patient's blood type.

Directed donation was initiated at the blood center in April, Burns said, in response to "the public concern about transmission of AIDS." About 2.3 percent of the center's blood collection now comes through the directed donation program, she said. (The Stanford Blood Center receives approximately 18,000 blood donations annually.)

Nationwide, there is controversy among blood bankers about such directed donation programs, largely because of the administrative expense and difficulty involved in keeping track of directed blood, and because there is fear that people will withhold giving unless they are specifically requested to do so.

Because the Stanford center's blood products go through only one transfusion service—supplying Stanford University Hospital and Children's Hospital at Stanford—directed donation poses much less difficulty here than it would for blood banks supplying many different facilities, Burns said.

The risk of transmitting AIDS through blood transfusion has been addressed in other ways at Stanford Blood Center. Last summer, the center began a unique program of T-cell screening all blood donations.

The screening method—which involves measuring the levels of certain white blood cells, called T-cells—is not selective enough to screen out only those donors with AIDS, according to Blood Center medical director Dr. Edgar Engleman. Therefore, some blood from healthy individuals is excluded from use. But Engleman estimated that the percentage of donors excluded is very low, between 1 and 2 percent. Most of these people do not have AIDS, he stressed.

HOSPITAL BOARD OF DIRECTORS APPROVES MODERNIZATION PROJECT COST

STANFORD—

A $110 million total project cost for the Stanford University Hospital modernization was approved by the board of hospital directors at a special meeting Wednesday (Jan. 18).

The board's approval, which includes borrowing plans, is only a recommendation to the general members of the hospital corporation, the university board of trustees. They will consider the proposal in February.

The hospital directors also recommended authorization to obtain construction bids for the project.

The directors approved borrowing up to $81.6 million through the California Health Facilities Authority for financing a portion of the project, with the remaining funds to come from private gifts and hospital reserves.

Initial borrowing for the project's first phase will be done on a short term basis until a guaranteed maximum price for the project has been obtained. The hospital direcTos and the general members of the corporation will then evaluate and approve the final form of borrowing.

First stage of the modernization project will begin late this spring with completion of an unfinished addition at the north end of the hospital. Then a new four-story building will be constructed to provide patient rooms, surgeries and other services. Existing areas in the hospital will be upgraded in a later stage.

Elvia Garwood, project director, reported that construction documents are now about 50 percent completed, and bids for construction work will be received between June and September.

Several options have been identified for the contract package, she said, in order to provide the most flexibility and allow the hospital to consider prevailing economic conditions, interest rates and other issues before awarding final contracts.

Options that would be considered if the project were reduced include shelling instead of completing certain portions of the new construction or deferring other portions.

The options would not affect plans for construction of new patient care units.

"Our primary goal is patient care," said Dr. Lawrence G. Crowley, vice president for medical affairs, "and our aim is to maintain in the project all of the new patient beds planned."

Hospital Board members also reviewed in detail financial feasibility and financing plans and a patient demand study.

Sheldon S. King, executive vice president and director of the hospital, presented strategies for more efficient hospital utilization, such as planned programs in renal transplantation, bone marrow transplantation, helicopter and trauma transport and preferred provider arrangements.

Dr. Dominick Purpura, dean of the School of Medicine, expressed the faculty's support for the project, and emphasized the importance off faculty involvement throughout the process of the modernization as it impacts academic programs.

STANFORD RESEARCHERS HARNESS HIGH TECHNOLOGY TO FIGHT PARASITIC WORMS

STANFORD—

Stanford University researchers are mobilizing some of the most advanced tools of medical research in the fight against a formidable, primitive, and often deadly foe—the worm.

It's not the garden variety of worm that concerns pharmacologist Dr. Tag Mansour and his colleagues, but its far more destructive cousins, the parasitic flat worms known as *Trematodes* that infect millions of people worldwide.

Worm infections—a scourge confined primarily to underdeveloped areas of the globe—have been consistently overlooked by Western medical science because the diseases are not a major problem in developed nations where most advanced medical research takes place, explains Mansour, who is chairman of Stanford's department of pharmacology.

Yet, the World Health Organization estimates that over 1.5 billion people suffer from infections caused by various parasitic worms. Approximately 220 million people have schistosomiasis, caused by the blood fluke *Schistosoma*; 650 million are infected with gut round worms called *Ascaris*; 450 million are afflicted with *Ancylostoma*, a type of hook worm; 250 million with the tissue round worms known as *Filaria*; and 20 million with *Onchocerca*, a parasite that causes the illness known as "river blindness."

No vaccines exist against any of the major parasitic worm infections, and once worm parasites enter the body it is very difficult to get rid of them. Symptoms of the various *Trematode* infections range from mild gastrointestinal discomfort to severe organ damage and death. Current drug treatments for worm-infested patients are inadequate because they follow the sledge-hammer approach: they harm the human host as they damage the worms.

In an attempt to develop new and effective drug strategies against worm invasions, Mansour and his coworkers are putting to work some of the newest and most sophisticated biological research techniques available: nuclear magnetic resonance (NMR), electron paramagnetic resonance spectroscopy (EPR), gene cloning by recombinant DNA methods, and monoclonal antibodies.

The long-term aim of this high-tech onslaught against worms, he explains, is to find drugs, or other agents such as monoclonal antibodies, that can kill the parasites while leaving humans unscathed.

The key is to find a specific characteristic of worm biology against which drugs or other agents could be aimed. Mansour's approach is to find differences between worm and human biochemistry. Once such differences are known, researchers can look for drugs or antibodies that selectively interrupt the biochemical machinery distinctive to the worms, leaving the human tissue undamaged.

The introduction of nuclear magnetic resonance (NMR) studies may help speed up the search for selective drugs against worm infections, Mansour reports. For the first time, using NMR, researchers will be able to "see" what is happening inside a living worm when it is exposed to various drugs. Up to now, drug effects on worm metabolism could only be measured indirectly by grinding up the worm and analyzing the extracted contents. But the extraction process itself masks researchers' ability to assess exactly the drug effects. With NMR, however, the scientists can measure drug effects on metabolism in an intact worm.

1-17-84

-more-

Mansour's research has shown that many enzymes (proteins that speed up chemical reactions in the body) essential for energy production in the parasites are different from those in the host. "These enzymes are good targets for prospective chemotherapeutic agents," he says.

He and his collaborators have also been using NMR to study these crucial enzymes in the live parasites and to observe their differences from the human host. In addition, NMR has helped the researchers identify phosphorus compounds in the intact parasites that were not recognized before. "These new chemicals give us hints about important reactions that are unique to the parasite and that can be manipulated pharmacologically," Mansour says.

In the search for biochemical differences between worm and human, the most promising target for drug or monoclonal antibody action that Mansour and his associates have so far found involves a molecule called serotonin. In humans, serotonin is a chemical messenger that shuttles between certain nerve cells in the brain. In worms, serotonin is a regulator of carbohydrate metabolism; it controls the worm's ability to break down substances that provide the energy necessary for growth and development, and it stimulates motility.

Serotonin plays its role, in both worms and humans, when it combines, lock-and-key fashion, with another molecule known as a "serotonin receptor." Mansour and his colleagues have discovered that the serotonin receptor found in the human brain is different from the worm's serotonin receptor. Thus, Mansour points out, it may be possible to find a drug to inactivate worm serotonin receptors selectively. This would shut down worm growth without harming the human host.

In the continuing drug search, Mansour's laboratory is also gearing up to use gene cloning techniques. Their aim is to generate large quantities of serotonin receptor protein. If large quantities of the serotonin receptor protein can be manufactured and studied, there is a better chance of finding just the right drug to inhibit it, Mansour says.

The first step toward accomplishing this is to isolate from worm DNA the gene that codes for its serotonin receptors, Mansour explains. Once this gene is found, it can be inserted into bacterial "factories" using recombinant DNA methods. These factories can then produce the large amounts of protein for study.

Once sufficient quantities of worm serotonin receptor become available, the protein could also be used to develop monoclonal antibodies to fight parasitic disease, Mansour suggests.

Antibodies are the body's roving agents that recognize foreign proteins and latch onto them, marking them for destruction by the immune system. Parasitic worms have devised clever ways to foil this natural immune response, Mansour explains. They camouflage themselves by coating their surfaces with protein from their human hosts or by changing their surface proteins periodically. Thus, the human's immune system never realizes the parasitic invaders are present. But treatment might be possible, says Mansour, if large doses of targeted monoclonal antibody were available to overcome the worm's defense system, particularly in its early developmental stages.

Mansour stresses that such treatments are, for the moment, hypothetical. Much more research and development remains. He has been studying worm infections for nearly 25 years, and bemoans the slow rate of progress against these diseases. But Mansour is also adamant about the need to vitalize and bring into the modern age of medical research a long-neglected major world health problem. His is one of only a handful of laboratories in the country using advanced research techniques to study parasitic worms.

Mansour's laboratory receives funding from the National Institutes of Health, and from the Edna McConnell Clark Foundation.

FOR IMMEDIATE RELEASE

EDUCATION AND SCIENTIFIC BENEFITS FROM CLEARCUT CARDIAC STUDY

STANFORD—

Clearcut evidence that lowering cholesterol levels substantially reduces the risk of heart disease is important educationally and scientifically, said the Stanford scientist who has been involved in lipid research for more than 20 years.

Dr. John W. Farquhar, director of the Stanford Heart Disease Prevention Program, said results announced Thursday from the national Coronary Primary Prevention Trial "emphasize the wisdom and the scientific validity for people to lower their cholesterol.

The 10-year study disclosed that lowering cholesterol can reduce the risk of heart disease by as much as 49 percent.

The results, involving 12 research centers including Stanford, were announced Thursday (Jan. 12) at a National Institutes for Health news conference in Bethesda, Md.

Farquhar, who with colleagues talked to the news media at a Stanford news conference, said these most recent results represent the culmination of his own lipid studies, which began 20 years ago at Rockefeller Institute in New York.

"Clearcut results such as have been achieved represent a medical milestone. I think the information we have learned during the past decade in this study will produce direct benefits in saving lives from coronary disease," Farquhar said.

"We have been telling people based on substantial evidence that it is never too early but never too late to reduce one's cholesterol level to reduce the risk of heart disease," he continued.

"It is highly appropriate that Stanford as a scientific leader played a role in this first major study to show conclusively that men at risk of suffering a heart attack will reduce that risk substantially by lowering their cholesterol levels."

Earlier research has shown that persons with a high level of cholesterol in their blood suffer more heart attacks than persons with lower levels. Other evidence has shown that it is possible to lower cholesterol levels.

But the evidence was unclear about whether persons whose level was high could benefit by having their levels lowered.

"This study should be excellent news for middle aged persons whose cholesterol levels are high," said Dr. Peter Wood, deputy director of the SHDPP. "The 10 years of research has shown that reducing the cholesterol level is clearly and irrefutably beneficial," said Wood, who like Farquhar began his cholesterol research two decades ago.

-more-

The current study was begun in 1972. Nearly 500,000 men were screened, and 3,806 men between the ages of 35 and 59 were selected as participants at 12 centers around the country. At Stanford, 356 volunteers participated in the study.

The volunteers, who all had high levels of cholesterol not lowered significantly by brief dietary treatment, were given either a drug, cholestyramine, to lower their cholesterol, or a powder which looked and tasted like the medication.

Neither the researchers nor the participants knew who was taking the drug and who was taking the placebo.

After seven years, the results showed that the risk of heart disease dropped in direct proportion to the amount of cholesterol lowering which occurred.

Farquhar said the statistical validity of the national study should convince scientists that large scale studies can be conducted effectively, producing results meeting the highest scientific standards.

The study cost $150 million. "But that compares with several billion dollars a year Americans spend on direct medical costs involving heart disease. If we can lower this by only a small fraction, we can more than pay the costs of this research," Farquhar said.

The NIH said that more than one million Americans suffer heart attacks each year, and more than 00,000 die as a consequence.

Farquhar noted that the lessons learned in the present study will be applied immediately in other SHDPP research, including a coronary risk education program currently underway in Monterey County.

Farquhar reminisced briefly about the years leading up to Thursday's announcement.

"I can recall the late evenings 13 years ago when Peter Wood and I sat down and started to write up the grant which culminated in this study," Farquhar said. "Since that time, the Stanford involvement has been enormous.

"For example, Dr. Wood's efforts at developing accurate methods of measuring cholesterol and his work at developing precise treadmill testing have had an important effect on this project as well as enormous spinoff potential in research and clinical applications. Dr. Stewart Agras of the psychiatry department worked very closely with us to develop counseling techniques to ensure that our dedicated volunteers would continue to comply with a very rigorous and longstanding program.

"The volunteers, whom we call 'partners in research' are really the great unsung heroes of projects such as these," Farquhar said.

Farquhar noted that trial director Dr. Dan Feldman, and trial coordinator Judith Halloran, "provided crucial leadership in making Stanford's record one of the most effective for volunteer compliance among the 12 centers.

WEIGHT CONTROL PROGRAM COMPARES DIET TO EXERCISE

STANFORD—

Dr. Peter Wood is looking for some good, but perhaps a bit flabby, men to help investigate what his own body has been telling him for nearly five decades—namely, that exercise is a better road to weight control than dieting alone.

Wood, a 54-year-old marathon runner and professor of medicine (research), is directing a study to test whether weight loss by dieting alone produces different effects on the body than weight loss by increasing exercise, not reducing food intake.

He suspects that people who try as a permanent way of life to adhere to strict diets without becoming more active are engaged in a painful campaign of placing the cart before the horse. And, he added, it's probably more difficult to measure and rigidly ration food intake—particularly on a long-term basis—than it is ultimately to adhere to an exercise program.

That opinion is based on extensive preliminary data, and Wood's own personal experience with regular exercise and as a runner for 47 of his 54 years.

"I eat more relative to my weight than the average sedentary person, and I burn off the calories.

"But review of the scientific literature indicates that the hypothesis has not been adequately investigated. When people ask for weight loss recommendations, we are unable to say that our strongly held views have been tested rigorously and scientifically," said Wood, who serves as deputy director of the Stanford Heart Disease Prevention Program (SHDPP).

About 80 moderately overweight and sedentary but otherwise healthy males, aged 30-59, in the Stanford area are already participating in the Stanford Weight Control Project, which is being conducted under a grant from the National Institutes of Health. Wood and his SHDPP colleagues are hoping to attract about 60 more participants to start the program as soon as possible.

"January, in the wake of New Year's resolutions and holiday partying, is a traditional time for beginning personal improvement programs. We're offering an organized, carefully monitored group environment," Wood said.

"We are not having major difficulty attracting volunteers," Wood said, "because many men are concerned about their weight. But many men have already started jogging, playing racquetball, or participating in other forms of play leading to weight loss. However, I'm certain there are many sedentary and overweight men in the area who have just now made up their mind to take action and are searching for a structured, supportive approach."

Wood said unique features of the program, which began signing up volunteers last September, are the intensity of professional assistance and monitoring offered to participants.

The program follows earlier studies at Stanford which showed that lean, middle-aged runners and tennis players ate considerably more than sedentary and often overweight men and women. The more active people burned off extra calories, and their appetites, while large, appeared much better synchronized with their physical needs than was true for sedentary persons.

"Americans since the early 1900s have actually decreased their food intake as they became more sedentary and more overweight. It's probable that the predominant problem for the majority of overweight people is exercising too little, not eating too much," said Wood.

In fact, Wood, who explains his theories in a book entitled *The California Diet and Exercise Program*, believes that it is more difficult on a long-term basis to control weight through diet alone, since a sedentary person in calorie balance needs to add only 14.4 extra calories a day to gain 45 pounds between ages 20 and 50.

"That's about a fifth of a banana too much each day, an amount the average person could hardly control one way or the other," Wood said.

"But exercise can clearly be controlled. And the average middle aged man can achieve reasonably quickly an exercise level—a 'play' level, really—affording him the opportunity to enjoy hearty meals with little fear that they will lead to excess pounds."

Wood believes the current study has the potential to do more than offer the scientific community and public possible evidence validating his theories. It can, he said, help determine whether persons who exercise to lose weight become generally healthier than those who diet without increasing exercise.

Also, the study will attempt to show whether persons who exercise regularly tend to adhere to their regimen more readily over a long period of time than persons who are placed on a diet-only weight control program.

Wood said that when volunteers join the program, they are given an extensive medical and physiological examination, including hydrostatic (underwater) weighing and treadmill fitness testing. These, he said, results in a detailed health profile. Next, general nutritional couseling is provided, and then participants are assigned randomly to one of three groups.

Group one embarks on a regular progressive exercise program without changing dietary intake.

"The activities are based initially on walking and slow jogging," Wood explained. "We're finding great variety in interest among the 80 volunteers who have joined so far. We shall organize running and cycling groups for these volunteers. We also encourage this group to 'play' frequently, either alone or with friends, outside the program."

A second group of volunteers is placed on a moderate diet program and asked not to alter existing exercise habits. A third group changes neither diet nor exercise habits, and thus serves as a reference group. After one year, each participant in this group will be offered what we believe at that time to be the best available weight loss program, Wood said.

In the second year of the program, contact between the program staff and volunteers in both the diet and exercise groups will be reduced. However, monitoring will continue periodically to determine which group adheres better to the educational program of the previous year, Wood explained.

For further information, call (415) 497-9646 between 2 and 5 p.m., Monday through Friday. Participants must be non-smoking males aged 30-59 who are now sedentary. Volunteers must fall within predetermined weight ranges. For example, 5-foot-10 men must weigh between 180 and 222 pounds with indoor clothes and without shoes. Potential volunteers should be willing to participate in any one of the three programs, and live or work reasonably near Stanford to ensure that visits of up to several times per week can be made conveniently during a one-year period.

The project is codirected by Dr. William Haskell, clinical associate professor of medicine, and coordinated by Susan Garay, R.D., M.S.-M.P.H.

Wood or Garay may be contacted directly by reporters at (415) 497-6254.

RENOWNED CARDIOLOGIST WILL DELIVER JOHN KENT LEWIS LECTURE

STANFORD—

Dr. Jay Cohn, professor of medicine at the University of Minnesota Medical School, will present the 17th annual John Kent Lewis Lecture Monday, January 23 at Stanford University School of Medicine.

The title of his talk, which begins at 5 p.m. in Stanford Medical Center's Fairchild Auditorium, is "New concepts in the pathophysiology and treatment of congestive heart failure." The lecture is open to the public.

Cohn, who is also head of the cardiovascular division at the Minnesota medical school—one of the country's outstanding centers for cardiac research—is widely known for his pioneering work in diagnosis and treatment of patients undergoing heart attack and heart failure. Cohn is an active researcher with over 200 scientific publications to his credit, and also serves on many national advisory committees and other professional organizations.

The John Kent Lewis Lectureship, first presented in 1964, honors the memory of Lewis, a cardiologist who obtained both his B.A. and M.D. degrees from Stanford. He went on to become a professor of medicine at Stanford Medical School, and devoted most of his professional life to medicine at Stanford, making important contributions to the study of heart sounds and cardiac arrhythmias. Lewis died in 1961.

Continuing medical education credit is available to physicians who attend the lecture.

GYN-OB CHAIRMAN RESIGNS POST TO CONCENTRATE ON RESEARCH

STANFORD—

Dr. W. LeRoy Heinrichs has resigned after seven years as chairman of the Stanford University Department of gynecology and obstetrics to devote fulltime to research, teaching, and patient care at the medical center.

"There comes a time for any scientist who has been temporarily immersed in administrative detail to return to more satisfying academic pursuits," said Heinrichs, 52, whose resignation, submitted Dec. 26, was accepted Thursday (Jan. 4) by Medical School Dean Dominick Purpura.

Dr. Kent Ueland, professor of gynecology and obstetrics will continue to serve in the post of acting chairman he has held since Heinrichs, who continues as a full professor, began a one-year sabbatical Oct. 1, said Purpura.

"We will be conducting a search for someone to lead the excellent department which LeRoy Heinrichs has built through careful, intelligent effort during his seven years as chairman," said Purpura. "I expect Dr. Heinrichs to serve as an active, vigorous participant in this search, while he continues the research already begun on his well-earned sabbatical," the dean added in a statement.

Purpura said he hopes to identify a new chairman before the next school year begins in October.

Since last October, Heinrichs said he has begun developing a reproductive biology research program within the department. The program investigates application of nuclear magnetic resonance (NMR) as a safe diagnostic tool for pregnant women. These studies have been conducted in laboratory aniamls with colleagues at the University of California, San Francisco while Stanford's NMR imaging facility is being developed.

"NMR offers the promise of diagnosing fetal health in new and possibly superior ways without the risk of radiation," Heinrichs said.

Heinrichs came to Stanford as full professor and chairman in September 1976 from the University of Washington School of Medicine, where he gained international prominence as leader of a research group working on the physiology, biochemistry and metabolism of the sex hormones related to reproduction. During his tenure here, Heinrichs served for two years as chairman of the National Institutes of Health's section on Human Embryology and Development.

Purpura pointed to the solid growth of the department's clinical activities and its return from a deficit to fiscal integrity under Heinrichs. The department's residency training program based at Stanford University Hospital (SUH) and at Santa Clara Valley Medical Center (SCVMC) was recently accorded a five-year certification—the longest duration granted by the certifying agency—under Heinrichs' leadership.

Educational innovations included several clerkship electives added to the curriculum for teaching medical students about the newer subspecialties within the discipline, and post-residency fellowships were developed for endocrinology-infertility, maternal-fetal medicine, and gynecologic oncology.

"Significantly," Purpura said, "we saw a small department with only modest clinical aspirations grow to become a significant force in the Medical Center and in regional and national medicine. The service which Dr. Heinrichs has headed for seven years has beocme a magnet, a quality care program as evidenced by the 400-500 mothers transferred in 1983 from Northern California and beyond to the two tertiary perinatal units served by the department's professional staff.

"Another major service that has been developed during Heinrichs' tenure as chairman is the gynecologic oncology program which attracts more than 400 new cases of cancer to the institution annually.

"The obstetrics and gynecology service has become an outstanding patient care and teaching component of our overall program. Heinrichs has not only developed the service but is recognized for superior clinical work, primarily in infertility and in gynecologic surgery," the dean added.

"While size is not in and of itself a measure of quality, I still believe it is worth noting that the Gyn-Ob department has grown from four to 16 fulltime faculty members and clinical staff during the seven years of Dr. Heinrichs' progressive leadership," Purpura added.

"One of this institution's strongest links with any affiliated hospital is the tie forged by Heinrichs between our gyn-ob department and the perinatal service at (Santa Clara) Valley Medical Center, where Stanford faculty, resident and students serve," Purpura added.

At Stanford University Hospital, the largest clinical facility served by the department, 3,000 newborn deliveries were performed in 1983 by the fulltime and clinical (community) faculty.

Heinrichs conceded that the department had been a focus of some controversy last summer following a personnel memo—later rescinded—in which Heinrichs had questioned a pregnant resident's request for scheduling personal time off. Purpura, who was then critical of Heinrichs' action, this month praised Heinrichs' "ability to face administrative problems by constructively appointing a faculty-resident committee to deal with stresses that are inherent in growing departments."

Purpura emphasized that Heinrichs had discussed with him his desire to concentrate on research prior to the memorandum incident.

The dean particularly praised Heinrichs' success at recruiting eminent senior faculty members as section leaders. These include Ueland, who is a nationally recognized expert on cardiovascular disease among pregnant women, and Samuel Ballon, an authority on reproductive cancers in women.

"And now Dr. Heinrichs will have his own opportunity to return to research agendas which have rested in the 'hold' bin for too long," Purpura said.

"In the coming years, we should have the possibility of diagnosing and then correcting a wide variety of maladies which afflict fetuses," Heinrichs said. "We anticipate the possibility of surgical or medicinal intervention of the fetus in the womb, thus increasing the odds of preventing or correcting problems before long term or potentially fatal injury has occurred.

"I feel confident that we have achieved the major goals I accepted with my wife's encouragement when I came to Stanford," Heinrichs said. "Now it is time to move on to the new challenge of strengthening the research programs in the strong clinical department that I have fostered."

In resigning the chairmanship, Heinrichs expressed appreciation "to the many, many persons in the department, the school, the clinics, the hospitals, and clinical faculty who aided in making my achievements possible."

CONFERENCE TO HIGHLIGHT CONCERNS AT BIRTH

Editors: Members of the news media are invited to cover this meeting, and should make arrangements by calling (415) 497-5763.

STANFORD—

"Perinatal Dilemmas: Mother and Infant in Focus" is the topic of the fourth annual meeting of the Mid-Coastal California Perinatal Outreach Program, sponsored jointly by Stanford's and Santa Clara Valley Medical Center's departments of gynecology and obstetrics, to be held Jan. 19 and 20 at the Doubletree Inn in Monterey, Calif.

The program is designed to provide physicians, nurses and other perinatal health care providers with current information on frequently encountered problems in the care of mothers and infants.

Topics include "Obstetric Analgesia Without an Anesthesiologist," "Cervical Priming and Induction of Labor," "Neonatal Asphyxia: Walk Through a Crisis," "Supporting Breastfeeding in the High-Risk Infant," "The Physical Consequences of Neonatal Intensive Care," and "Medical-Legal Dilemmas: Suits I Have Known," among others.

Faculty from Stanford include Dr. George Albright, director of obstetric anesthesia; Charlene Canger, clinical social worker; Dr. Philip Sunshine, director of newborn nurseries; Rose Grobstein, chief pediatric social worker; Dr. Paul Hensleigh, chief of the perinatal consultation service at Santa Clara Valley; Barbara Petree, clinical nursing coordinator in labor and delivery; and Dr. Kent Ueland, chief of maternal-fetal medicine.

Joining the Stanford group will be Dr. Robert Burnett, president of the California Medical Association, as well as specialists from Santa Clara Valley, other hospitals, and private practice.

The Perinatal Outreach Program (MCCPOP) has developed educational programs throughout an eight-county region (San Mateo, Santa Clara, San Benito, San Luis Obispo, Monterey, Santa Cruz, Stanislaus and Alameda). It disseminates information and services to achieve quality care for all pregnant women and newborns, optimum utilization of highly trained personnel and intensive care facilities, assurance of cost effectiveness, and higher standards in regional perinatal centers.

MCCPOP includes a perinatal resource center, a genetic counseling center, and a birth defects center, as well as providing emergency consultation and transport, perinatal nursing preceptorships, and intensive care nursery preceptorships.

A registration fee will be charged participants of the upcoming conference, which has been approved for continuing education credit. For further information and registration materials, call Kim Leadon at (415) 497-5763.

NATIONAL CHOLESTEROL STUDY RESULTS DISCUSSED LOCALLY

STANFORD—

(Editors: The Stanford Heart Disease Prevention Program (SHDPP), which sponsored the Coronary Primary Prevention Trial at Stanford, will hold a news conference at 11 a.m. Thursday, Jan. 12, at the SHDPP labs and offices, 730 Welch Road, Palo Alto, CA 94304. Researchers, other staff members, and several of the 356 volunteers who participated locally in the study will be available to discuss the national results, as well as the local program. Results of the study will be made available at a national news conference at the National Institutes of Health, Bethesda, Md. at 8 a.m. PST. Local researchers and participants will NOT have results prior to the national announcement but tape recorded proceedings of the national news conference will be available for playback at the SHDPP following the local news conference.)

Researchers may be one step closer to solving the mystery behind the leading cause of death in the United States when results of a federally-sponsored cholesterol study are released next Thursday (Jan. 12), said Dr. John W. Farquhar, who directed the Stanford component of the research.

The study closely followed thousands of volunteers deemed likely candidates for heart attacks for at least seven years to test the relationship between high blood cholesterol and coronary heart disease (CHD). Strong evidence has led many physicians and researchers to believe that high blood cholesterol contributes significantly to heart disease. But earlier, shorter studies have not given researchers the definitive evidence considered necessary to show whether lowering high cholesterol levels will reduce the risk of heart disease, said Dr. Dan Feldman, the trial director for the Stanford component.

Even this week, as results of the Coronary Primary Prevention Trial (CPPT) were being readied by the National Heart, Lung and Blood Institute in preparation for the Jan. 12 Washington, D.C.-area news conference, researchers were cautious about whether the current $150 million federal study will offer a definitive answer on the issue of cholesterol.

"Realistically, we're hoping that this study will bring us closer to an answer," said Feldman.

He will learn the results of the study shortly before he appears with colleagues and some of the 356 Stanford volunteers at a news conference scheduled at 11 a.m. next Thursday (Jan. 12), shortly after the national results are to be announced in Washington.

Nearly 500,000 men were screened after the study was devised in Washington in 1972. Twelve medical centers in the United States and Canada selected 3,810 men between the ages of 35 and 59 who were found to have high levels of cholesterol which were not lowered significantly by brief dietary treatment. These were men considered at high risk of suffering a heart attack or contracting coronary heart disease.

Half of the men were given daily doses of a drug called cholestyramine, which has been shown to lower serum cholesterol levels. The other volunteers were given a placebo, a dummy powder which has no effect on cholesterol levels.

Neither the participants nor the researchers knew who was receiving the drug and who was taking the placebo to ensure that results would be objective. Participants will be told in personal interviews during the next three months whether they received the drug or the placebo.

Before taking part in the research, the men had all been instructed on how to maintain a healthy diet, Feldman explained, but otherwise they were told to continue their lives as before. Periodically, blood samples were sent to researchers for analysis.

All of the volunteers were male, because statistics have shown that they are far more likely than women to develop heart disease.

The men's physical health was monitored, and the incidences of heart disease in the cholestyramine and placebo groups were compared to see if lowering cholesterol lowered the incidence of heart disease.

"All the evidence we have been accumulating for several decades indicates that a longer, heart disease-free life is much more likely if one is able to control serum cholesterol level," said Farquhar. "But since heart disease develops over a period of many years, it is very difficult to prove conclusively that decreasing one's cholesterol level will reduce the risk of heart disease. Hopefully, this study will contribute to such evidence."

Farquhar believes that many heart attacks could be prevented by lifestyle changes and/or administering anti-cholesterol drugs prior to middle age. He said he is confident that with additional evidence, people will be better motivated to make changes.

Cholesterol is a vital component of the cell walls, and a component of other body chemicals. However, in excess quantities it can clog blood vessels and interfere with the efficient flow of blood as well as the effective pumping of the heart.

The cholesterol level of many men can be lowered effectively by avoiding foods rich in animal fats. But to conduct a study based on diet would have been prohibitively expensive and time consuming, said Feldman.

ARCHITECT SELECTED FOR CHILDREN'S HOSPITAL

STANFORD—

The San Francisco firm of Anshen and Allen has been selected as architect for the New Children's Hospital at Stanford, announced Langston G. Trigg, Jr., project director.

The firm was recommended by a selection committee to the New CHAS Board of Directors after an intensive nationwide search. The selection was also approved Feb. 15 by the Stanford University Hospital Board of Directors and by the Children's Hospital Board on Feb. 28.

Selection of the architectural firm is a major step in the planning to consolidate the pediatric facilities of both institutions, said Dr. Lawrence G. Crowley, chairman of the New CHAS Board. The new hospital will be built at an estimated $40 million project cost and will be located adjacent to new construction planned at Stanford University Hospital (SUH).

The New Children's Hospital will consolidate the 60 beds at Children's and the 44 pediatric acute medical-surgical and pediatric intensive care beds at SUH. It will also house the Stanford-Children's Ambulatory Care Center, which provides 27 separate clinic services. It will continue to provide inpatient services in the specialties now offered by both hospitals.

Anshen and Allen, based in San Francisco for more than 40 years, have designed the Lawrence Hall of Science in Berkeley and the Lawrence Livermore National Laboratory, the Coronado Bridge in San Diego, John Muir Hospital in Walnut Creek, the International Building and the Bank of California Headquarters in San Francisco.

Approximately half of the firm's projects are in the health care field. Medical clients include Alta Bates Hospital in Berkeley, Children's Hospital in San Francisco, University of California Medical Center in San Francisco, Sacramento Medical Center, and Community Hospital of the Monterey Peninsula.

Derek Parker, senior principal and president of the firm, will head a proposed architectural team that includes a health planner, architectural programmer and a former pediatrics nurse.

The selection committee was "unanimous and enthusiastic in their recommendation," said Trigg. "We feel Anshen and Allen can provide the professionalism and creativity necessary to assist in our goal to create a world class institution."

PEDIATRICIAN STRESSES SAFE RIDING

Editors: Photos available upon request if not included.

STANFORD—

Pediatrician James Flippen recalls the terrible car accident which one of his patients, a 5-year-old child, survived without a scratch, having been buckled safely by a seat belt in the back seat.

"That car turned over several times and went down an embankment," said Flippen, a clinical associate professor at Stanford Medical Center. "The mother had a seat belt on and was only injured a bit. The father wasn't buckled in, though. He went right through the windshield and was seriously injured."

The story is one of endless accounts which illustrate the importance of seat belts, as well as car seats for the very young. In fact infancy is the best time, Flippen contends, to impress upon parents the importance of automobile safety for their children.

"At that stage, parents are very aware of the delicacy and susceptibility to injury of their newborn. So it's the best time to sensitize them to using safety devices for now and the future."

After the first few months of life, car accidents account for the greatest number of fatalities among all ages, and cause the deaths of more children than the next five killers—diseases and accidents—combined, Flippen said.

California law since about a year ago requires families to use car seats for infants and children up to 40 pounds and four years of age. (Almost all states now have similar laws.) A state survey conducted earlier showed that only one out of 10 children was being properly restrained in the car, with the rates at 20 percent below age one, 9.8 percent from one to four, and 3.6 percent from five to 14 years old.

"It became clear that a law was necessary," said Flippen, who chairs the Accident Prevention Committee of the American Academy of Pediatrics (AAP) for Northern California. "First Ride, Safe Ride" became the slogan for the AAP's drive to educate the public to the need for infant car seats.

In the state of Washington, Flippen said, there was not one death for an entire year among all properly restrained children under five.

-more-

2-28-84

"In general, 90 percent of deaths and 80 percent of serious injuries associated with auto accidents in children under five can be prevented by the use of car seats and seat belts." Flippen explained that most injuries occur because of contact within the car or because passengers are thrown out. Safety devices can prevent both by stabilizing the position of the passenger.

At Stanford University Hospital, a committee exploring the car safety issue organized and approved a car seat loaner program, which is now administered by the Community Association for the Retarded in Palo Alto. The program helps families that can't afford to buy infant car seats, by loaning them out on deposit, with most of the sum refundable upon return. Privately funded, the program has almost 100 seats available, fitting babies up to six or nine months old.

For families that can buy their own seats, the hospital has an arrangement with Norneys at the Stanford Shopping Center, Flippen said, whereby the store will deliver a seat upon request from the maternity unit. Otherwise, parents can pick up the seats at most toy or department stores, he noted.

Last week the well-baby nursery at SUH sponsored Infant Car Seat Safety Week as a consciousness-raising effort. "I think the hospital has a moral responsibility to encourage the use of these seats upon discharge," said Candy McKinley-Cole, clinical nursing coordinator of the unit.

Flippen said that the California law requiring car seats is enforced similarly to defective equipment laws. If a car is stopped for another reason and found to contain an unrestrained child, a citation is issued. The fine is then cancelled if the parents show evidence that a seat has been obtained and put to use.

At some point the AAP may push for stricter enforcement, he said, if evaluation of the law's success demonstrates a need. "Probably there will soon be some impact on insurance claims with regard to recovery for injuries," he noted.

"We'd like to see a law like this for all ages, such as some countries have," Flippen added, "but it's very difficult to get through the legislature." A recent push to impose a curfew on teen driving between 1 and 5 a.m. failed, he noted, even though in other states with such laws the auto accident rate for 16- and 17-year-olds has been cut by 60 percent.

But safety awareness and legislative efforts will continue, Flippen said, as emphasized by the AAP's latest theme: "Make Every Ride a Safe Ride."

MATCHMAKING BOOSTS STANFORD HOSPITAL'S VOLUNTEER RECRUITMENT

STANFORD—

Voluntarism has been on the decline in recent years, but Stanford University Hospital is meeting the challenge of recruitment by reviving an old idea—matchmaking.

"The idea," explained Sharon Beckham, coordinator of volunteer services, "is to find people who haven't been in the mainstream of voluntarism and carefully match their interests with those of the hospital.

"Volunteers want to feel their talents being put to good use. And they want to receive satisfaction from what they give.

"For us this means knowing what the hospital's volunteer needs really are, and converting them into tasks that will attract people of different skills and interests."

Beckham, who came to Stanford from the University of California in San Francisco, is the first to hold the volunteer coordinator's post in the Community Relations Office directed by Jeanne Kennedy. Beckham is a professional with more than 15 years in volunteer management work.

For the past six months she has been evaluating hospital volunteer needs, developing new procedures, and familiarizing the staff with them.

"Because of tough economic conditions in recent years," Beckham acknowledged, "many women have joined the work force to maintain a certain level of family income. Since volunteers have been traditionally women this trend has reduced their availability.

"But what hospitals are now finding out is that many other types of individuals, including more men, would be willing to serve if one knows what motivates them and acts on that information."

A clear need for a hospital is flexible scheduling to avoid excluding potential volunteers, Beckham said. Some people are free during evenings, others on weekends and holidays. And there are students, professional people and senior citizens whose time commitments and special interests must be taken into account.

For example, a man came to the hospital recently to see Beckham. He was highly trained in the computer field. He was interested in volunteer work, he told her, because in his spare time he needed to be involved in an activity with a humanistic touch.

"Another visitor was a registered nurse who is an administrator in home care," Beckham said. "What she had missed most in her job was hands-on nursing experience. She wanted volunteer work to retain contact with hospitalized patients."

-more-

Feb. 23, 1984

Stanford University Hospital has had a long tradition in voluntarism provided in part by the Stanford Medical Center Auxiliary. Since 1959 this organization of nearly 336 active and 224 former members is credited for providing 1,642,000 service hours to the hospital and its patients.

Beyond the needs of patients, Beckham said, the auxiliary has generously donated funds to meet emergency needs of patients and their families, scholarships and loans to young doctors in training, physical therapy students and junior volunteers. And it has given the hospital $1,191,000 in gifts for special programs and purchase of equipment.

But in recent years the auxiliary, like its sister organizations at other hospitals, had noted a drop-off in membership. When Jeanne Kennedy became director of community relations at the hospital in 1980, she assisted the auxiliary in its recruitment of new members.

In 1982 a special committee of the board of hospital directors conducted an analysis of volunteer needs at the hospital. The committee recommended the hiring of a full-time professional to coordinate activities of volunteer groups, to determine departmental needs where volunteers are needed, and to assist in recruitment efforts.

To date, this approach has not only attracted new types of volunteers, but has augmented auxiliary efforts and participation in new programs, Beckham said. One of these is the innovative "Lifeline," a personal emergency response program which connects frail elderly and handicapped people with their neighbors and the hospital in emergencies.

Lifeline is a joint project of the auxiliary and community relations based in the hospital's emergency department. The auxiliary provides staffing and it gave funds to get the project started.

Among volunteer groups now at the hospital are the Patient Relations Associates who assist people when they are admitted to the hospital and also serve as patient advocates. There is the Junior League of Palo Alto, Inc., whose members work with the hospital's emergency department to provide cardiopulmonary resuscitation training both in the hospital and specified community locations. There is the Volunteer Translators Bank with more than 80 members to help doctors and Stanford's patients from other lands communicate, and the Chaplaincy Office Volunteers who give spiritual support to patients and families.

Taking a different form are the volunteers of the Palo Alto Art Club whose art exhibits help enhance the hospital environment as well as pre-meds and other students who volunteer in order to get exposure to the health care field.

Besides her continuing recruitment efforts, Beckham said, she will work actively to enhance the volunteers' image and to improve understanding of their increasing importance to the institution.

"Volunteers are unique individuals," she said."They provide a needed human dimension, especially in a hospital with a very busy staff trying to get the job done."

If you are interested in volunteer opportunities at Stanford hospital, Beckham is ready to help. Her phone is (415) 497-7424.

RED CROSS PRESIDENT DISCUSSES TRANSPLANT ROLE

STANFORD—

The president of the American Red Cross said Wednesday (Feb. 22) that his organization may have an educational role in helping to create a national climate making organ transplantation the norm.

Richard F. Schubert, currently on a national tour of some of the 3,000 American Red Cross chapters, participated in a luncheon meeting with Stanford University Hospital administrators, surgeons and staff members of the heart and heart/lung transplant team, as well as faculty involved with a planned kidney transplant effort. Also attending the meeting were leaders of the Red Cross' Palo Alto Area Chapter.

"As I travel around the country," Schubert said in an interview following the meeting, "the issue of 'can't some part of John or Mary's body be used' is raised constantly.

"If you create a climate in which this (organ donation) is as acceptable as giving blood, it would make an enormous difference, because it would become a routine question rather than an exceptional question," Schubert said.

Specifically, he said, education would make it easier for physicians and others to broach the subject of organ transplantation to family members of potential donors.

In some cases, he said, the grief of donors' families can be somewhat mitigated by the knowledge that a part of their loved one lives on and could be used to extend life for someone else.

"I think there is an enormous amount of emotional appeal. in saving a life from a life that has been lost," said Schubert. "It is a very appealing concept."

Dr. Stuart Jamieson, assistant professor of cardiovascular surgery and head of Stanford's heart/lung program, said after the meeting that "since we're critically short of donors, any help at all that we can get in making people aware of this need will be most helpful."

Jamieson and surgical colleagues have said a shortage of donors is the most critical obstable to making transplantation available to more people who face certain death within a short time without the procedure.

Schubert said the Red Cross currently is directly involved in bolstering university hospital transplant programs in St. Louis and Minneapolis. Bone and skin are stored at blood banks, and the local Red Cross chapters are directly involved in helping to match donors and recipients.

A potential program Schubert said he discussed briefly with Stanford administrators was the possiblity of the Red Cross' involvement in distributing or facilitating donor cards for employees.

But he told the Stanford gathering that the national organization, which claims 1.5 million volunteers nationwide must be careful to proceed cautiously with transplant involvement, since a new program "does divert resources from other potential benefits to the community unless you enlarge the cadre (of volunteers and donors) to pick up this new responsibility."

In a later interview, Schubert added that "I like to believe that there are people out there who would support this (organ transplantation) who might not support something else." But he said that it is an unaswered question which must be researched.

Schubert, who has served as Red Cross president since January 1983, is a former steel industry executive. He has served in government, including three years as solicitor of the Department of Labor.

REID TO GIVE CREASY PHARMACOLOGY LECTURES

STANFORD—

Dr. John Reid, the William N. Creasy Visiting Professor of Clinical Pharmacology, will present a series of lectures at the medical center Feb. 27 through March 1.

Reid, regius professor of materia medica at the University of Glasgow, Scotland, is internationally recognized for his research in hypertension and the pharmacology of the adrenergic receptor system. He will give the following lectures:

- Feb. 27—"Alpha Adrenoreceptors: Classification and Regulation," noon in R358;
- Feb. 29—"Catecholamines, Potassium and Arrhythmias," 4 p.m. in M112;
- March 1—the Creasy lecture, "Hypertension and Pregnancy: Mechanisms and Management," 8:30 a.m. in Fairchild Auditorium.

The lectures are free, and the public is invited.

Reid is the author of over 200 articles related to his own research interests and co-author of books on clinical pharmacology and hypertension. He is also editor of *Clinical Science*.

The Creasy professorship is awarded yearly to several host medical schools and visiting professors nationwide. It honors the late William N. Creasy, former president and chairman of the Burroughs Wellcome Fund, which sponsors the professorships.

For more information on the lectures, call the clinical pharmacology office at (415) 497-7801.

STANFORD EMBARKS ON CANCER RESEARCH PROJECT WITH CHINESE PROVINCE

STANFORD—

U.S. university scientists and researchers in a Chinese province will be searching jointly for the causes of colon and rectal cancer.

By comparing a group of genetically similar individuals, in this case ethnic Chinese, in two contrasting cultures—North America and the People's Republic of China—researchers are hoping to discover whether diet or lifestyle affect the risk of contracting colon and rectal cancer.

To accomplish the task, thousands of ethnic Chinese will be interviewed in both countries about their diet and exercise patterns to learn if these factors have any influence on the cancer rate.

Alice S. Whittemore, a professor (research) in the Stanford department of family, community and preventive medicine, said Chinese-American residents—including about 400 colon/rectal cancer sufferers and approximately 1,000 controls—will be interviewed in San Francisco, Los Angeles, and possibly Vancouver, British Columbia.

Whittemore said several hypotheses will be tested, including the possibility that increasing the intake of dietary fiber and cruciferous vegetables—including cabbage and mustard plant—protects against colon/rectal cancer, while alcohol and low intake of vitamins A, C and E increase risk. Also to be studied is the possible benefit of exercise in lowering the risk.

In China, both cancer sufferers and their neighbors who are free of the disease will be interviewed in Zhejiang Province, a tea and silk producing region near Shanghai, where the rate of colon/rectal cancer is high by Chinese standards.

The four-year study undertaken by Stanford University and the University of Southern California was approved recently for $958,000 funding by the National Cancer Institute. In China, research is being conducted by the Zhejiang Medical University with funding provided by the Zhejiang Provincial Bureau of Public Health, said Tom Fingar, director of the Northeast Asia-United States Forum on International Policy at Stanford, the group which helped organize the venture.

"This program is unusual," said Fingar, "because it involves an agreement between U.S. universities and regional health officials and their scientific colleagues in China. Neither national government was involved in the negotiations. Researchers in both countries were eager to insulate the study from the vicissitudes of international politics."

The provincial Chinese government involved will pay local costs. "We wanted a project where the potential gains would be so important that China would be willing to commit precious foreign exchange funds," Fingar said.

-more-

2-22-84

"An interesting phenomenon," Whittemore said, "is that the colon/rectal cancer rate is lower in China than here. But the Chinese who emigrate to this country get this form of cancer as often or perhaps a bit more often than other Americans. We are attempting to find out why."

While differences in data collection make it difficult to compare cancer rates in the United States with China, figures show the incidence of colon cancer to be more than five times greater for ethnic Chinese men in San Francisco (36 cases annually per 100,000 population) than for Chinese in Shanghai (seven cases yearly per 100,000).

Chinese figures show that rectal cancer is the fifth and colon cancer the sixth most prevalent cause of cancer (stomach cancer is the greatest) among Shanghai Chinese. Among Chinese males in San Francisco, colon cancer is second only to lung cancer in prevalence.

Among all Americans, colon cancer is the third most prevalent form of cancer, accounting for 87,000 cases in 1983, according to the American Cancer Society. A total of 39,000 new rectal cancers were reported in the United States in 1983.

Whittemore said length of time in the United States or the number of generations a person has been in this country will be studied to learn if the risk of cancer changes.

"We're hoping for important scientific results," said Fingar, "but even if we come up with no answers, the project is still a marvelous opportunity to gain insight into life, administration and local politics in China." A feature of the study, said Fingar, is that all raw data will be available to researchers from both countries.

Already, the two years of intricate and successful negotiations to develop the joint project have done much to undermine the "pretty widely held perception that you can't work with the Chinese." When it is apparent that the project has compelling mutual benefits, negotiations proceed efficiently and cordially, Fingar said.

Chinese and U.S. scientists will travel to each other's countries, Fingar said. For example, a Chinese pathologist will be coming to Stanford to work with American counterparts to synchronize medical data.

"We want to be absolutely certain that we mean the same thing as our Chinese colleagues when we describe the site or specific nature of a cancer," Whittemore explained. "We want to make sure we are comparing the same things."

Nutritionists from both countries have been working together to develop dietary questionnaires which are compatible.

Fingar said the project was born in 1981 when Stanford cancer expert Henry S. Kaplan, noting increasing cooperation and contact between the two superpowers, expressed the desire to launch a joint cancer research project. (Kaplan died Feb. 4 knowing the project had been approved.)

The Louise and Y.T. Lum Foundation of Honolulu, Fingar said, provided a grant to help launch negotiations, and a series of meetings were held among Fingar; his co-director, John Lewis; and Li Bing, deputy director of the institute of oncology in Beijing.

Ultimately, said Whittemore, colon/rectal cancer study was selected by scientists and officials in both nations for scientific and administrative reasons.

-more-

Epidemiologically, colon/rectal cancer offered a good study model because while prevalent in both nations, its rate in the United States was much higher.

"We had thought of several other forms of cancer common in the United States," Whittemore said, "but when we reviewed statistics, we found that they were almost nonexistent in China, making it impossible to find suitable subjects. We needed a difference between the two countries in the prevalence so that we could operate on the premise that environmental factors were involved, but we also needed enough cases to make a study possible."

A bureaucratic and procedural advantage, Fingar said, was that primary responsibility for studying colon/rectal cancer had been assigned to provincial officials.

"Several forms of cancer assigned to the central government for study would have made it more difficult to work directly with local health professionals."

Working with Whittemore at Stanford are Marion Wu, a research associate and coordinator of the project; Ralph S. Paffenbarger Jr., an epidemiologist and professor of family, community and preventive medicine; and Michael Hendrickson, associate professor of pathology.

At the University of Southern California, primary researchers are Brian Henderson, professor and chairman of the preventive medicine department, and Anna Wu, an assistant professor in the same department.

"The project was both conceived and implemented," Fingar said, "because Stanford has a unique combination of a very strong medical school program and the Northeast Asia-United States Forum on International Policy, which exists to bring together expertise from other parts of the university and appropriate counterparts in Asia."

Editors: Fingar may be contacted at (415) 497-9742, Whittemore at (415) 497-5460.

BULIMICS NEEDED FOR PSYCHIATRY STUDY

STANFORD—

Women 18 and over with bulimia, the binge/purge eating disorder, are needed to participate in a Stanford study to compare the efficacy of two medications in treating the syndrome.

There is evidence that a particular anti-depressant as well as a specific appetite suppressant, administered under close supervision, may be helpful in treating bulimia, said Betty Kirkley, who is coordinating the study in the behavioral medicine clinic.

The researchers need 36 participants, who will be assigned randomly into three groups for 16 weeks, one group receiving a placebo. After initial screening, volunteers will come to Stanford once a week for four weeks, then every other week for 12 weeks, for about 20 minutes each time, so that progress can be monitored by the prescribing psychiatrist.

Volunteers accepted into the study will be required, at their expense, to undergo a physical examination by their physician. All other aspects of the treatment will be provided free of charge.

If any group has done better than the others at the end of the study, Kirkley said, the more effective treatment will be offered remaining participants through another clinical trial.

Women who are pregnant, planning pregnancy during the study period, or nursing should not enter the study. Nor should women join who have hyperthyroidism, seizure disorders, alcoholism, glaucoma, or history of heart disease.

The principal investigator is Dr. Stewart Agras, professor of psychiatry. For further information contact Kirkley, at (415) 497-5869.

ADVANCE FOR RELEASE A.M. THURSDAY FEB. 23 TO COINCIDE WITH PUBLICATION IN *NEW ENGLAND JOURNAL OF MEDICINE*

STANFORD RESEARCHERS REPORT FINDING ON LYMPHATIC DISEASE IN HEART TRANSPLANT PATIENTS

STANFORD—

A new finding that sheds light on the nature of cancers developed by organ transplant patients was reported by Stanford University School of Medicine researchers Thursday Feb. 23.

The discovery could lead to new information about lymphomas—cancers of the immune system—and also help guide treatment strategies for transplant patients who develop lymphatic disease, said Dr. Jeffrey Sklar, assistant professor of pathology at Stanford University School of Medicine.

What the researchers discovered is that, in a group of ten heart transplant patients who developed an abnormal lymphatic condition, all ten had a cancerous form of the disease.

The research was conducted in Sklar's laboratory by Dr. Michael Cleary, a postdoctoral fellow. Dr. Roger Warnke, associate professor of pathology at Stanford, also collaborated in several phases of the study. Their results were reported in the February 23 issue of *The New England Journal of Medicine*.

Development of lymphatic disease is a known complication of organ transplantation, explained Sklar. Patients receiving immunosuppressive drugs to halt the body's rejection of the foreign organ following surgery are 40 to 50 times more likely than the general population to develop such diseases, he said.

Among heart transplant patients from Stanford, approximately 7 percent of those receiving conventional anti-rejection drugs have developed a form of lymphatic disease characterized by abnormal and sometimes fatal proliferation of lymphocytes, the immune system's antibody-producing cells.

The incidence of lymphatic disease has been almost twice as high, or 13 percent, among heart transplant patients receiving cyclosporine, a powerful and effective anti-rejection drug, Sklar said.

But lymphocyte proliferation could be caused by a viral infection or a cancerous process, and so there has been considerable debate among medical researchers concerning the nature of these "lymphoproliferative lesions," Sklar explained.

Some researchers have argued that the disease is a malignant lymphoma, or cancer. Others believe that the lymphocyte proliferation is a viral disease, something like a "runaway" case of infectious viral mononucleosis. "For a variety of reasons, this controversy has been difficult to settle," Sklar said.

There is no disputing, however, that these lesions are severe and progress rapidly, he observed.

In order to select the best treatment for patients who develop the disease, physicians need to know whether the disease is cancerous or an infection. If it is cancerous, then anti-cancer radiotherapy and chemotherapy are appropriate, Sklar noted; if the disease is infectious, then anti-viral drugs may be important.

-more-

What Sklar, Cleary and Warnke succeeded in doing was to use a "fingerprinting" method that can distinguish between malignant and infectious disease of the lymphocytes. With the method they showed that ten out of ten heart transplant patients had a malignant form of lymphoproliferative disease.

"This has important implications for treatment of transplant patients," Sklar and his colleagues reported. They suggested that transplant patients who acquire a lymphoproliferative disease should undergo the "fingerprint" test. If their disease is found to be malignant lymphoma, then anti-cancer therapy such as radiation treatment or chemotherapy should be "instituted at the earliest possible time, perhaps in combination with reduced immunosuppression," the researchers continued.

The researchers stressed that their findings should not discourage potential transplant recipients from pursuing treatment. "Although the high frequency of lymphoma in organ transplantation is an important problem, new approaches to therapy are being tried, and ways of reducing the risk of lymphoma may be found. Organ transplantation remains a very important form of therapy for certain patients with endstage diseases."

In addition to the immediate clinical benefit in being able to demonstrate that lymphoproliferative disease in transplant patients is malignant, the discovery could help in basic research attempts to understand the underlying biology of cancer, Sklar emphasized.

"These tumors can help us learn more about how lymphomas develop, and how the immune system normally acts to suppress malignancies," he said."Often, studying rare tumors leads to new insights into more common forms of cancer."

The research method used—originally developed by Cleary and Sklar—is called immunogenotyping. It relies on the fact that different lymphocytes in the body have slightly different arrangements of their genetic material, DNA. The scientists have found a way to detect each lymphocyte's special DNA arrangement, which is much like a "fingerprint."

The method also takes advantage of a fundamental difference between cell proliferation caused by a viral infection and cell proliferation associated with cancer.

A cancer, or malignancy, develops when something goes awry in a single cell, Sklar explained. That cell divides, giving rise to identical daughter cells, which again divide, and so on. The result is a "clone," or a proliferation of many cells all of which came from the original deviant cell. "Thus, cancer is a monoclonal disease," Sklar explained.

A viral infection, on the other hand, is "polyclonal," Sklar said. The virus may stimulate cell duplication, and at the same time, the viruses can spread from cell to cell. Thus, the disease arises separately in many different cells.

The researchers took lymphatic tissue from ten heart transplant patients who had developed lymphoproliferative disease. They examined the DNA "fingerprints" from the patients' diseased lymphocytes. In each case, they found the patient's proliferating cells had identical "fingerprints." This meant that each patient's disease was monoclonal, and therefore malignant.

The research was supported by grants from the American Cancer Society, the National Institutes of Health, the Jane Coffin Childs Memorial Fund for Medical Research, and the John A. Hartford Foundation.

UNIVERSITY TO NEGOTIATE RESEARCH SPACE LEASE AND AFFILIATION WITH HOWARD HUGHES MEDICAL INSTITUTE

STANFORD—

A recommendation authorizing Stanford University's vice president for business and finance to negotiate leasing medical research space to the Howard Hughes Medical Research Institute has been approved by the board of trustees.

The leased space of up to 30,000 net square feet will be part of the now planned $45-million Center for Molecular and Genetic Medicine (CMGM), according to the recommendation of the Committee on Academic Affairs and Development. The building will be located on land adjacent to the medical school, with construction expected to begin sometime in 1984.

CMGM, which will contain 70,000 net square feet, will house the laboratories of a new major academic program in molecular and genetic medicine--a broad-based effort to understand how the basic molecules of living things contribute to health and disease, said Dean Dominick P. Purpura of the School of Medicine.

The 40-year lease arrangement will provide advance rent payments from the Miami-based Hughes Medical Institute to begin construction of a portion of the CMGM building this year while other fundraising efforts for the structure are under way.

In addition, Purpura said, an affiliation agreement will be signed between the medical school and the Hughes Medical Institute covering such issues as faculty autonomy and other academic concerns. Hughes investigators will be employed by the institute, but their faculty status will be determined by Stanford medical school criteria. Only individuals meeting the criteria of both institutions will be appointed.

"In this respect," Purpura explained, "arrangements will be similar to those in place between Stanford and its affiliated Palo Alto Veterans Administration Medical Center in which Stanford faculty have employment status."

Stanford, as other major research universities, has had a long relationship with the institute founded by the late Howard M. Hughes to advance human knowledge in the field of the basic sciences (principally the field of medical research and medical education).

Under the program four senior Stanford faculty members were supported by the Institute as Hughes Fellows for eight years. The program came to an end two years ago because of lack of laboratory space.

In recent years, Purpura said, the Hughes Medical Institute has begun to establish long-term relationships with a number of distinguished universities, including Harvard, Yale, Columbia, Duke, and the University of California in San Francisco.

"Like the proposed arrangement now explored by Stanford, agreements between the institute and universities involve long-term leases of laboratories and placement of faculty in them to conduct medical research," Purpura said.

The CMGM building is expected to house the research of about 35 faculty members.

If agreements with the institute are signed as expected, up to eight of the faculty members will be Hughes institute investigators.

INFANT CAR SEATS A MUST

STANFORD—

Infant Car Seat Safety Week will be held at Stanford University Hospital Feb. 21-24, as a consciousness-raising effort to promote the use of the seats among new parents.

A display each day from 11 a.m. to 1 p.m. near the main center cafeteria will include bumper stickers, actual car seats for demonstration, and information about buying and renting infant car seats.

Auto accidents account for the highest number of fatalities among babies under one year old. In California, it is the family's legal responsibility to use a car seat for any child up to four years old or 40 pounds.

"I think the hospital has a moral responsibility to encourage the use of these seats upon discharge," said Candy McKinley-Cole, clinical nursing coordinator of the well-baby nursery, which is sponsoring the week's activities.

For further information, call McKinley-Cole at (415) 497-6776.

NEW STUDY TO TEST INTERFERON'S ABILITY TO PREVENT CANCER RELAPSE

STANFORD—

Interferon, the protein that was initially—and prematurely—hailed as a "miracle cure" for everything from cancer to the common cold, may find an important niche in preventing cancer rather than curing it.

Stanford researchers are beginning a study of the substance's ability to prevent relapses in patients whose cancers have been controlled by conventional anti-cancer drugs.

The study, to be conducted in patients who have cancer of the lymphatic system, will take advantage of interferon's anti-growth properties and effects on the immune system which may prevent malignant growth, said study leader Dr. Sandra Horning, assistant professor of medicine at Stanford University School of Medicine.

Traditional anti-cancer drugs are more effective than interferon in treating lymphoma, but because they kill non-cancer cells as well as malignant ones they are too potent to be used on a longterm basis for prevention of cancer relapse, Horning explained.

Interferon wields more of an anti-growth effect rather than a "killer" effect, with the ability to slow growth in tissues where cells are dividing, she said.

Interferon also seems to play a "watchdog" role in the body's immune system, constantly on the look-out for abnormal cells. Thus, its natural role might enable it to zero in on and halt growth in small pockets of cancer cells at an early stage of relapse, Horning suggested.

Horning's colleagues on the study are Stanford professors of medicine, Drs. Saul Rosenberg and Thomas Merigan. Rosenberg is head of Stanford's oncology division and Merigan is head of the division of infectious diseases.

"This is the first study in the world to examine what may turn out to be a very important use of interferon," Rosenberg said.

The form of lymphoma to be focused on—low-grade non-Hodgkin's lymphoma—accounts for approximately 10,000 new cancers in the United States each year, Horning estimated.

Conventional chemotherapy initially can control this form of lymphoma in 75 to 80 percent of patients treated, Horning said. However, none of these patients is likely to be cured and approximately half will experience a relapse of lymphoma by three to four years following the chemotherapy, she added.

2-14-84

-more-

Interferon has shown moderate anti-cancer activity when used alone in patients with this form of lymphoma, Horning explained. But it is less effective than conventional anti-cancer drugs, such as cyclophosphamide, vincristine and prednisone, she said.

Patients accepted into the program will receive conventional chemotherapy—or may already be undergoing such treatment—to bring their cancer under control, Horning explained.

Once the cancer recedes, the patients will be divided randomly into two groups, one of which receives interferon and the other a control group receiving none of the experimental drug. The interferon patients will receive daily injections of the substance for one month, followed by a three-month rest period. Then they repeat the one-month on, three-months off cycle three more times.

All patients will be followed and the rate of relapse compared in the interferon and control groups, she said.

Patients need not stay in the Stanford area during the study, Horning said, because interferon treatments may be administered near home by a physician, nurse, family member, or even by patients themselves. However, during each of the four on-interferon months, patients will have to return four times to Stanford so that various tests may be performed.

Possible side effects of interferon include fatigue, appetite loss, chills and fever, Horning said. Usually, these can be eliminated or controlled with simple over-the-counter remedies, she noted.

The study will last several years; about 50 patients per year will be accepted in the trials, Horning said. It is best if interested patients are referred to the study by their physicians, Horning said. Inquiries should be directed to research nurse Pat Gilman at (415) 497-5877 or 497-5777.

Several different kinds of interferon are known, all with potentially different benefits and applications, according to Horning. The type to be used in this study, she explained, is known as "alpha-interferon;" in the body, alpha-interferon is produced naturally by white blood cells.

However, because naturally produced human interferon is extremely difficult—and expensive—to purify, the researchers plan to use pure, genetically engineered interferon instead.

Genetically engineered interferon is produced by inserting a human gene coding for alpha-interferon into bacteria, which can grow rapidly and spew out large quantities of the protein, Horning explained. The interferon has been manufactured by the drug company Hoffmann-LaRoche, Inc., she said.

The study is funded by a grant from the National Cancer Institute.

MATHEMATICIANS/PSYCHIATRIST EXPLORES BEHAVIOR FROM A UNIQUE PERSPECTIVE

STANFORD—

Roy King never thought he'd end up a physician. He was studying in the Harvard University library one summer, doing research for the doctorate in mathematics he received from Cornell University. The librarian whom he'd often seen working approached him one day and said: "You don't seem to have the personality of a mathematician. You seem much more sociable."

That observation stuck in King's mind, he recalled. "I mulled over it for a few months and decided to try medicine."

At Stanford University Medical School, King never thought he'd end up a psychiatrist. It was during his rotations that he "fell in love with psychiatry. My mind works by putting a lot of facts together and synthesizing ideas," he analyzed. "Psychiatry is very liberating in that you have to consider many different aspects of a person—psychological, social, biochemical, pharmacological—and put them all together in order to make a diagnosis."

After getting his M.D. in 1979, King did a psychiatry residency at Stanford, which he finished in 1983. For the past two years as a post doctoral fellow and, starting in September as an assistant professor, King has been researching human behavior in a way that only a few are capable of. By combining his expertise in math and psychiatry, King has made himself, and his research, unique in the medical field.

Others are quickly becoming aware of his special qualities. His work on the measurement of external potentials of cell membranes was patented by General Electric. The young physician has already published more than 20 articles in professional and technical journals, including one coming out this month in the prestigious *Proceedings of the National Academy of Sciences (PNAS)*. Most recently, King received a two-year, $120,000 grant from the Robert Wood Johnson Foundation's Minority Medical Faculty Development Program to support his work.

King's research has focused on understanding the functions and effects of neurotransmitters, chemicals released in varying amounts by the brain that are known to affect behavior. In the current PNAS article, King, and coauthors Drs. Jack Barchas and Bernard Huberman describe the mathematical equations they've developed as a model to illustrate the erratic behavior in schizophrenic patients.

Existing models, King said, show that schizophrenic patients suffer from either too much or too little of any neurotransmitter. When King began observing patients' behavior, which often changed from calmness to violence within minutes, he quickly realized that a permanent defect in neurotransmitter levels did not adequately account for the conditions.

"What occurred to me was that their behavior, if anything, showed more variability, more fluctuation than normal behavior. It wasn't a matter of too much or too little of a chemical," King explained in his animated way.

Using nonlinear models mathematicians have created during the last 10 or so years, the scientists developed equations that provide a model of the unstable behavior that schizophrenic patients exhibit.

In other projects, King has been looking at specific neurotransmitters: dopamine, norepinephrine and serotonin. After measuring these chemicals in up to 100 individuals, King believes there may be a seasonal variance in their levels. For example, he explained, dopamine and norepinephrine levels seem to be higher in the winter than in the spring. This may account, he continued, for the more anxious and introverted feelings many individuals experience during the winter.

"What we don't know is if people are more active in the spring and that leads to changes in neurotransmitter levels, or if the seasons can predict behavior," King said.

The coming school year will see King treating patients in the clinic and teaching psychiatry residents as well as doing research. Hectic as the three activities may seem, they fit together well in King's mind. "In seeing patients and doing research I use similar tactics," he explained. "I have to gather all the information I can, get some type of global impression, and then start to pick apart all the facts."

And how does teaching fit in? "That's easy," King replied laughing. "I just like to talk a lot."

SCHEMING OF HUMAN BRAIN HELPS OVERCOME LANGUAGE IMPAIRMENT

STANFORD—

Speech and language disorders that follow strokes or other brain injuries can be treated with more success than previously thought possible, contends Dr. Jon Eisenson, a Stanford professor emeritus of hearing and speech science.

To treat aphasia, a pathological disorder suffered by at least 50 percent of stroke patients, Eisenson in the course of his counseling has developed several approaches based on ideas set forth in his revised book *Adult Aphasia*, second edition (Prentice-Hall, 1984).

Aphasia is characterized by some loss of speech, reduced comprehension of language, and problems in reading and writing. Not limited to stroke victims, it can be caused by any insult to the brain, including brain tumors, hemorrhages, embolisms, head penetrating wounds, or—in the case of some children—congenital disorders.

Eisenson's treatment approach is based on the knowledge that the human brain is divided into right and left hemispheres, the left appearing to be involved with details and analytical functions, and the right hemisphere being more "intuitive," dealing with totalities.

Eisenson, a neuropsychologist and psycholinguist, illustrates his ideas with this example:

Think of a song you know very well. Try reciting the words silently to yourself, without the melody in mind, and stop when you first stumble. Now try it with the melody—you should get further.

The significance of this exercise goes way beyond its seeming simplicity, Eisenson said. Music and melody fall under the right hemisphere's jurisdiction. His treatment approaches for aphasia victims take into account the potential scheming of the human mind, which, in the case above, has elicited help from its right hemisphere to achieve a usually left hemisphere function: language.

"Even the most severely impaired aphasic's recovery can be enhanced if the significant role of the brain's right hemisphere is recognized," Eisenson said in a recent interview.

-more-

2/8/84

"Speech intonation and inflection are melodic functions," he explained, "so perhaps language produced with exaggerated intonation might improve the aphasic's linguistic functioning. Since as far as we know brain tissue that is destroyed does not regenerate, recovery probably involves a reorganization of the brain so that healthy tissue takes over the function of destroyed and unhealthy tissue."

His approach supports the observation that left-handed and ambidextrous persons have bilateral control of language, and are thus less likely to incur aphasia unless there is damage to both hemispheres of the brain. Even when they do incur linguistic impairment, their outlook is in general better than right-handed individuals, more than 95 percent of whom control language in the left hemisphere, Eisenson said.

Left-handed individuals comprise 10-11 percent of the population; the ambidextrous only 1-2 percent.

One method Eisenson developed, to be published soon in a series *Reading for Meaning (A Syntactic-Semantic Approach)* (Modern Education Corp., 1984), involves teaching the aphasic to read without requiring the detailed segments of syllables, words and grammar. Instead it uses complete phrases, series of images and other visual illustrations. "These are based on grammatical constructions normal children acquire as they learn to speak," he noted.

He utilizes any method that will maximize the patient's potential while helping him to achieve communication on a level with his new capabilities. "Rather than insist on returning to the former level of ability, a good therapist can help the patient be as effective a communicator as possible under the circumstances."

This attitude can lead to better retrieval of language, whereas insisting on full conventional speech at the outset often leads to frustration. Future research, he said, should emphasize ways to approach the most severe aphasics with non-oral communication—signing, pointing, pictures—at the onset of language disruption. "We err when we use as a last resort that which should probably be used first."

"No patient should be given up on, no matter what," added Eisenson. "It's important to improve assessment criteria so that therapists can better anticipate prognosis and approach of choice. Each patient unto himself—that's the rule."

More likely to affect older persons, aphasia can be misdiagnosed, mistaken for senility or other afflictions of old age, such as loss of memory for names of events, things, people and places, Eisenson said.

Aphasia tends to affect more men than women. "This is in part related to factors like hypertension, hazardous working conditions, sports, and the fact that in general, males are more prone to neurological impairments than females," he added.

-more-

The recovery rate for females is better too. The right and left hemispheres of female brains are believed to be not quite as differentiated in function as are those of males. Unless there is bilateral damage, the healthy hemisphere can more easily take over the functions of the injured one.

But the question of who will recover, when, how well, and how remains a very individual matter. Can doctors, lawyers, writers who have suffered from aphasia expect ever to go back to their lives as before?

"With many the answer is yes indeed," Eisenson said. "There is, however, a wide range of recovery, related to a person's age (the younger the better), sex, amount of damage incurred, and onset of treatment."

The earlier treatment is begun the better, he said. Recovery—which can take from six months to the rest of one's life—usually includes some degree of spontaneous language retrieval during the first three months after onset.

This will occur even in the absence of direct treatment, Eisenson said, and probably relates to a recovery of the brain cells surrounding those that were damaged. There are drugs that can accelerate this improvement, he noted.

Oral apraxia, a separate but related disorder, often accompanies aphasia. This, Eisenson said, is an inability to articulate, or to program the brain to produce the sequence of sounds the individual has in mind. "It's like a young child saying 'pasketti' for 'spaghetti,' but exaggerated because the patient makes error after error."

Those suffering from severe aphasia, apraxia or both should never be spoken to in an infantile way, Eisenson emphasized.

Therapy must take into account the patient's personality traits—both previous and those resulting from the impairment—as important factors. Eisenson also stresses group and family counseling for aphasic patients.

"Aphasia is really a family problem," he said. "If properly counseled family members can help a lot, whereas well-intentioned but unguided, they can do harm." This stems in large part from the emotional, financial, and other adjustments they all must make when faced with the new situation.

Eisenson is former director of the now defunct Scottish Rite Institute for Childhood Aphasia at Stanford. A prolific writer, he has also recently authored *Aphasia and Related Disorders in Children* (Prentice-Hall, 1984).

MEDICAL SCHOOL SPONSORS SCIENTIFIC SYMPOSIUM FEATURING STUDENT RESEARCH

STANFORD—

Organelles slither across cellular cytoplasm; tiny beads coated with a muscle protein rocket down long cables only a few molecules wide.

You can see it all take place on videotapes by Ronald Vale, a Stanford University medical student.

This microscopic look at the way muscle proteins work will be just one of the features at the first annual Stanford Medical Student Research Symposium Friday February 17 in Fairchild Auditorium at Stanford University School of Medicine.

The symposium was organized to give students engaged in original scientific research an opportunity to report on, and discuss, their results with other students, faculty, and interested members of the community, explained Dr. Robert Cutler, professor of neurology and associate dean for medical education.

The pursuit of research is an important component of medical education at Stanford, Cutler explained. The faculty senate of the medical school declared in 1980 that the school intends to develop students' capacities for leadership in the clinical practice of scientific medicine, and to provide opportunites for students to prepare for careers in research and teaching in the various branches of basic, clinical, and social medicine.

Approximately 75 percent of medical students at Stanford engage in research, Cutler noted.

"Stanford provides a unique environment compared to most other medical schools," explained Donald Hangen, a second-year medical student. "Every effort is made here to encourage student research."

Hangen, who is giving a poster presentation on his research project, helped organize the symposium along with John Stevens, also a second-year student. "We felt it would be a good way to help medical students share their research experiences," Hangen explained.

"We hope that the symposium will give the Stanford community exposure to the quality of research done by Stanford medical students," added Cutler.

-more-

The program begins at 8:50 a.m. and ends at 4 p.m. followed by a reception in the auditorium lobby. To encourage attendance at the event, which is sponsored by the medical school dean's office, all medical school classes have been cancelled for the day, Cutler said.

The symposium, modeled after a professional scientific meeting, will consist of 12 oral presentations and 15 poster displays covering a full spectrum of medical research, he added. Selected faculty members will participate with brief discussions following each student presentation.

The program is divided into two morning and two afternoon sessions. Molecular genetics and regulation of the immune response will be the focus of the first morning session, followed by a period for looking at poster displays in the auditorium lobby. Neurobiology will be covered in the early afternoon, followed by a session on research advances in clinical medicine.

Cutler noted that for some students, the symposium would provide a first opportunity to publicly present research results. For other students more advanced in their careers, scientific meetings are familiar haunts. By the time they graduate, many Stanford medical students have already published articles in prestigious journals and participated in international scientific meetings.

All medical students were invited to submit summaries of their research last fall. A committee of faculty and students then selected the symposium participants, taking into account factors such as students' seniority and achieving a balanced blend of research topics.

Much of the student research conducted at the medical school is supported by scholarship funds from the Stanford Medical Alumni Scholars program, Cutler noted.

Cutler thinks that this symposium will be the first in an annual tradition. Although he is highly pleased with the quality and number of presentations this year, he hopes to see a greater representation next year from students conducting research in the areas of health care delivery and clinical medicine.

FOR IMMEDIATE RELEASE

HENRY KAPLAN, CANCER RESEARCH PIONEER, DIES

STANFORD—

Henry S. Kaplan, an internationally renowned radiologist and cancer research pioneer at the Stanford University School of Medicine, died at his home Saturday, Feb. 4, after a five-month bout with cancer.

Death came peacefully at 10 p.m., according to his family.

The 65-year-old professor of radiology, who was a non-smoker, had undergone surgery in October for removal of a lung tumor. He had made a satisfactory recovery from the surgery, but he continued radiotherapy treatments for alleviation of pain.

Ironically, unlike other cancers for which Kaplan had developed effective treatments, lung cancer remains a big killer, he explained in an interview before his death.

"The best thing one can report about it is 12 percent survival. The problem is metastasis," he said. "We know very little about how this cancer spreads in the body, except for general distribution patterns."

In the last 40 years, he said, cure rates for lung and cancers of the pancreas and esophagus have remained equally unchanged at one and two percent respectively.

"Even before I got sick," Kaplan said, "I looked at this picture as dispassionately as I could. Overall I came down somewhat on the pessimistic side."

The grim statistics, Kaplan added, provide a measure of the scientific challenge that still exists.

Kaplan, who lived on the Stanford campus, is survived by his wife, Leah, who is a psychiatric social worker and director of the Stanford Help Center, a counseling center for university employees. They have two grown children, Ann and Paul.

Memorial services will be held from 3 to 4 p.m., Sunday, February 12 at Fairchild Auditorium of the Stanford School of Medicine.

Last December, in recognition of his major contributions to the university and to society, the Stanford University Board of Trustees approved a resolution creating the Henry S. Kaplan Professorship in Cancer Biology.

The resolution recognized Kaplan as an "exemplary teacher, a world-renowned scientist, and a distinguished caring physician."

The establishment of the endowed chair, the resolution added, will permit the medical school to attract a senior scientist to carry on Dr. Kaplan's work and to head his Cancer Biology Research Laboratory.

Kaplan is best known for his contributions to clinical medicine, and as the co-inventor of the first medical linear accelerator in the Western hemisphere.

Judging correctly that the effectiveness of radiation treatment was limited by the crude and low-powered x-ray machines then available, Kaplan in the early 1950s suggested that the linear accelerator, an experimental tool used by atomic physicists, might be adapted for cancer therapy.

-more-

The linear accelerator shoots particles down a tube to a target. When the beam of particles collides with the atomic target, a burst of energy that includes x-rays and other forms of radiation is produced. These x-rays could be harnessed and aimed to deliver controlled bursts of radiation to areas of tumor growth in the body.

He talked to former Stanford professor and now trustee Edward Ginzton and others at a luncheon in San Francisco.

"It sounded miraculous," Kaplan recalled, "and not only had I convinced myself, but at the end of the luncheon I had convinced all of them. I told them this would become the radiotherapy machine of the future."

Along with Stanford physicists led by Ginzton (now board chairman of Varian Corporation), Kaplan helped design the cumbersome machine into a useful apparatus and performed the first experiments.

But building the machine wasn't easy.

"Unlike the young researchers we recruit today, who are handed everything on a silver platter," Kaplan said, "it took us two years in the richest country on earth to raise $150,000."

The six-million-volt machine was eventually constructed on campus and moved to San Francisco, where the medical school was then located. Then a new problem came up.

"Before we could assemble it," Kaplan said, "it was clear we had to have protection from its beam."

J. Wallace Sterling, then president of Stanford, went to the Irvine Foundation for help. A meeting was arranged in San Francisco.

At the time it was publicly known that Stanford was preparing to move its medical school from San Francisco to Palo Alto in four years. Kaplan told the foundation people that if they helped him to install the machine in the city, a great deal could be learned in the interim.

"This is like a rifle," Kaplan told them. "The past machines have been like shotguns. We're going to have to learn our profession all over again. We're going to have to work out technical procedures that have never been done before. The opportunity to have four years to do that is crucial."

With a $75,000 foundation gift, Kaplan built a tiny concrete box into a hillside in what is now the Pacific Medical Center. It was well protected and had a hatch on top because he knew that someday he would have to bring a crane along to pick the machine right up through the ceiling and bring it to Palo Alto.

In 1955 the machine was installed. A team of physicists calibrated it. And the great day came when Kaplan was ready to turn on his machine on a patient.

"The true story is stranger than anything I could have made up," he said. "We had had bull sessions about what kind of cancer patient would be our first referral. The first was a child with retinoblastoma in the only remaining eye. Surgeons had already removed his other eye for the same type of cancer.

"I don't think I will ever forget the puzzled look on the face of the garage owner down on Fillmore Street when I asked him to borrow a heavy duty automobile jack, and then explained that it was to carry a huge block of lead with a pinhole in it, to enable us to position that pinhole daily for six weeks directly opposite the tumor in the baby's eye while missing the lens and cornea. The boy is now in his twenties and doing well, with his vision in the treated eye intact."

Today, medical linear accelerators are the cornerstone of radiation therapy. The machines are found in cancer treatment centers and hospitals worldwide. Kaplan's pioneering work in radiation therapy has led to notable gains in treating a wide variety of cancers, from tumors of the prostate to those of the urinary bladder, nasopharynx, testicles, ovaries, and childhood retinoblastomas.

-more-

But in no malignancy have the gains been more dramatic than in Hodgkin's disease, a cancer of the lymphatic system. In association with Dr. Saul Rosenberg and other colleagues, Kaplan devised an aggressive diagnosis and treatment protocol combining radiation, chemotherapy and surgery.

This multi-pronged treatment program has turned Hodgkin's disease around from a hopeless illness to a more than 80 percent curable disease. Today at Stanford, more than 85 percent of Hodgkin's patients survive seven years after diagnosis, and 75 percent are permanently cured. In children, survival rates soar to 96 percent alive 11 years past diagnosis, and 93 percent of treated children never experience a relapse.

In addition to lifesaving clinical gains, Kaplan has made important discoveries in cancer biology. His most important are studies of mice exposed to x-rays and chemicals. Kaplan found that the leukemias and lymphomas the mice developed were caused by a latent virus activated when the radiation or chemical agents suppressed the body's normal immune system function.

Demonstrating that viruses cause lymphoma in animals gave hope to researchers that a viral cause of cancer may be found in humans as well.

Kaplan contributed to another important area—monoclonal antibodies, originally produced from mouse cells by Cesar Milstein and Georges Kohler in England in 1975. These are proteins from the immune system capable of recognizing highly specific target cells in the body and marking them for destruction by the immune system. The idea has excited scientists who see their potential as "magic" bullets for locating and destroying cancer cells in patients. In 1980, Kaplan's group reported it had produced a similar pure antibody protein from cultured human cells. This achievement was considered an important milestone since the human protein might be more desirable than a mouse product for actual cancer treatment.

Throughout his career, Kaplan earned a reputation as a cogent critic of the medical school and university administration. Among his many battles was to get the university to recruit outstanding faculty leaders for the Stanford medical school after its 1959 relocation from San Francisco. Among them were Arthur Kornberg and Joshua Lederberg. The two received Nobel prizes, "and because of that," Kaplan said, "Stanford was catapulted literally from a second or third-rate medical school into some kind of mysterious but very exciting place that students thought of in the context of Harvard." Because of a greater emphasis on research, Stanford soon joined the ranks of a dozen or so medical schools generally regarded as setting the pace in American medical education.

Kaplan was born April 24, 1918, in Chicago. His lifelong commitment to combatting cancer began when he was only 15 and suffered the loss of his 45-year-old father to lung cancer. Then a high school senior, the young Kaplan soon went on to the University of Chicago, earning his undergraduate degree at age 20 in 1938. He obtained his M.D. from Rush Medical College in 1940 and went on to complete internship and residency training at Michael Reese Hospital by 1943, as well as acquiring an M.S. in radiology from the University of Minnesota in 1944.

Kaplan subsequently held positions at Yale University and the National Cancer Institute in Bethesda before joining Stanford University School of Medicine as professor and chairman of the department of radiology in 1948, a position he relinquished in 1972. While holding the post, Kaplan brought innovation and acclaim to the department, not only through his clinical and scientific work but in teaching practices as well.

In recent years Kaplan held the Maureen Lyles D'Ambrogio professorship and directed the Louis B. Mayer Cancer Biology Laboratory, continuing biological research. Some new, important work in this connection will be published in the coming months.

As a clinician, Kaplan saw many patients regularly, developing unusually close relationships with many of them. In 1982, more than 400 of Kaplan's former Hodgkin's disease patients and their families attended a reunion at Stanford to mark 20 years of successful clinical trials against the disease.

-more-

Among Kaplan's many awards several stand out. In 1969, he received the Atoms for Peace Prize, the only physician to be so honored. In the same year he also received the Shahbanou Award from the Lila Motley Cancer Foundation, the Order of Merit from Italy, and he became a Chevalier in the French Legion of Honor. In 1971, Kaplan received the L.L. Villiers Award from the Leukemia Society of America, and in 1972 he was given the American Cancer Society's Annual National Award as well as becoming the first radiologist to be elected to the National Academy of Sciences. In l975, he was elected an Honorary Fellow of the Royal College of Radiologists, United Kingdom. In 1978, he received the Lila Gruber Cancer Research Award, and in 1979 he became the first recipient of the prestigious Charles F. Kettering Prize from the General Motors Cancer Research Foundation.

In the political sphere, Kaplan has been a vocal proponent of human rights. In 1978, he and other prominent cancer researchers led a boycott of an International Cancer Congress held in Buenos Aires, and staged "a counter congress" in Paris to protest repression of human rights in Argentina.

When asked what he would like to be remembered for, Kaplan replied, "My accomplishments that stand the test of time such as the work on Hodgkin's disease and malignant lymphomas. That is an area where there will be continued further improvement, but I think we contributed a foundation stone which today is leading to cure worldwide of hundreds of thousands of patients.

"It's hard for me to know whether my work on mouse virus or radiation-induced lymphomas will be remembered or not. I happen to think it's very interesting, but I have the feeling people tend to gloss over it.

"I'd like to be remembered as the co-developer of the medical linear accelerator for cancer treatment, which today is a standard of excellence throughout the world. And not just for developing the machine, but the standards for its use. They are part and parcel of that development.

"I'd like to be remembered for my service on the National Cancer Advisory Board in 1960 at a time when the number of radiotherapists in the United States was about 120, and the number of physicians in radiotherapy training was only 18. Today, as a result of these efforts, there are close to 2,000 board-certified radiation therapists.

"Those are the accomplishments. As for the rest, I'd like to be remembered as somebody who has been basically kind and deeply concerned about his patients, and very humane in dealing with them.

"At the same time I'd like to be remembered as somebody who was tough enough to be willing to fight the battles with a number of deans—battles needed to create and maintain high standards, not just for our department but for the Stanford medical school. I fought more battles that had nothing to do with radiology than almost anybody in the school.

"So viewed from one side, I think I was a kindly physician, a role model. Viewed from another, I was perhaps a malignant son-of-a-bitch who drove deans to despair and was known as a dean killer. These two kinds of things were sort of hard to reconcile. But I must confess, I never enjoyed fighting with deans, I never enjoyed it for a minute. It took an awful lot out of me. Yet if I believed I was right, I didn't care how hard I fought.

"I'd also like to be remembered as somebody with a reasonably good sense of humor, with a love of art and music and literature, and hopefully as a good husband, a good father, and a loyal friend."

The family would prefer memorial contributions to be made to the Henry Seymour Kaplan Professorship in Cancer Biology or to the Henry S. Kaplan Commemorative Sculpture that will be sited on the medical center campus as a tribute to his contributions to science and medicine. Checks can be sent to the Development Office of the School of Medicine, 780 Welch Road, Room 106, Palo Alto, California 94304.

FOR IMMEDIATE RELEASE

STANFORD—

CITY DESKS: In an interview before his death Henry S. Kaplan, Stanford's cancer research pioneer, discussed his views on the future of cancer research, national cancer policy, and the philosophy which guided his work.--Ed.

Throughout his 35-year career at Stanford, Henry S. Kaplan, who died of cancer Saturday, Feb. 4, remained an influential force in the policy counsels of the Stanford medical school.

An astute and tough-minded clinician-scientist, he reigned supreme as chairman of the department of radiology from 1948 through 1972, as one of the engineers of the medical school's consolidation on the Stanford campus in 1959, and more recently as director of the Louis B. Mayer Cancer Biology Laboratory.

Nationally, Kaplan exerted an equally important influence as a member of a group of top-flight academic scientists, foundation officers, and government officials who have dominated the directions of national cancer research policy during the past 20 years.

In a rare interview before his death, Kaplan discussed these years and some of his views, with the characteristic candor that has distinguished him all his life.

On the future directions of cancer research:

"Many of the newer radiobiological approaches have been tried. One approach that hasn't been tried well is the use of radiosensitizers, chemicals that may render tumors more amenable to radiation therapy. They may not pan out out as an effective treatment. But we need studies to prove this point, and our people are doing this work now.

"The second area of future development is hyperthermia interacting with radiation. Its underlying mechanisms are not well understood. This approach could be an enormous success, but we don't know that yet. The use of new machines that permit heat to be directed more deeply within the body might provide answers.

"A third approach depends on external beam radiation combined with interstitial radiation. It's an approach that does less overall damage to the tissues while affording a good probability of eradicating the tumor.

"The technique is used with the greatest effect in early breast cancer. This I think is a big development. The method makes it unnecessary to remove all the breast. All that needs to be removed is the small lump. It's a most appropriate treatment for women with small lumps. Many women will refuse to go to their doctor until the lump is too big and their chances of saving the breast have been seriously reduced. If they knew they did not have to lose a breast by a procedure that offers the same long-term survival, they would come forward early. I see this development pushing radical surgery for breast cancer into a much more restricted frame.

"I don't foresee any other major thrusts in radiotherapy, just as I don't see any in chemotherapy, except with the advent of new drugs that are really effective and not too toxic. The last really good drug was cis-platinum, introduced 12 or 15 years ago. That says to me that it isn't easy to find new drugs that really have a different mode of action and are free of toxic effects.

-more-

"Beyond that, there's excitement in oncogenes or cancer genes. It may be that some brilliant molecular biologist will be smart enough to figure a way to 'neutralize' the effects of their abnormal expression and 'put the cancer to sleep' so to speak. That's a possibility, but it's obviously a very speculative one.

"We may also make progress in understanding cancer due to viruses where we have a potential handle on the disease. The identification of a human T-cell leukemia-lymphoma virus by Robert Gallo at the National Institutes of Health is an important step. This virus occurs in a selected group of T-cell leukemias and lymphomas in Southern Japan, the Caribbean basin, and adjacent shores of North and South America. That's fascinating and important, but it accounts for a very tiny amount of the total problem.

"And we have monoclonal antibodies to cancer-related antigens. This is an important development that could have promise in cancer therapy. If I were well, our program would be oriented in a strong way toward trying to develop such antibodies. I realize this is exceedingly difficult. But antigens capable of stimulating human white cells do exist in many cancers, and that would be the direction I'd like to see followed.

"With these exceptions, I cannot really see any major new directions from which big increments in the results of cancer therapy are going to come. I looked at this as dispassionately as I could before I got sick, not just now that I could take an unduly pessimistic view."

On national cancer research policy:

"The biggest problem I see is the politicization of the boards called upon to make decisions at the federal level. Today, the National Cancer Advisory Board is a heavily politicized body with relatively little scientific competence. That was not true 15 or 20 years ago. Each president in recent years has carried this one step further, and Mr. Reagan has really done it much more than before. Now, we have Republican businessmen and Republican writers and conservative right-wing thinkers, all pronouncing judgments on how funds for cancer research should be allocated, while a tiny, handful of very frustrated, competent scientists on the board cannot get their opinions through.

"An example of this in recent years was the political influence of people who argued we must identify every mutagen in the environment. Today, we know that most mutagens are not cancer-inducing so that a lot of that thrust was false and unwarranted. Structural rearrangements of chromosomes are meaningful in cancer and what brings them about is an important area of future research, but it's outside the general meaning of the term, mutation.

"This politicization has not yet happened at the lower echelons of the National Cancer Institute. The boards of scientific counselors of the different branches are still made up entirely of scientists and physicians, and they function well. How long it will last is unclear."

On what makes a great academic clinical department:

"When I became chairman of radiology at Stanford in 1948 there was not a single radiology department in the world in which there was scientific research. The only thing called research for radiologists was to sit on their butts in front of a viewing box and look at film and perhaps collect one or two cases of some rare malformation. I felt it was very important for diagnostic and therapeutic radiology to have an experimental as well as a clinical base. I insisted on having a laboratory from the start. I felt intuitively that it was no good having a department chairman make big speeches about how important research is and himself do no research whatever. I insisted on doing research myself and demanded the same of everybody. But it was a given that the quality of patient care in the department had to be absolutely first class."

SUPPORT GROUPS: GETTING BY WITH A LITTLE HELP FROM FRIENDS

STANFORD—

When Sue Peterson left Stanford University Hospital after giving birth about seven years ago, her twins weighing less than three pounds each stayed behind.

"The emotional impact of having to leave our babies in the hospital for nine weeks because of complications due to their premature births was devastating," she recalled recently. The boys, Benjamin and Bradley are healthy now but then, "my husband and I felt like we were the only ones in the world that who were experiencing this. There was no one else to talk to, no one whom we felt really understood."

So about a year ago, Peterson, with the help of one of the hospital's social workers, formed a support group for parents of preemies and infants in the intensive care nursery. "Our main purpose is to provide an opportunity for parents in similar situations to share their feelings, lend support, and learn to feel comfortable about their infants' conditions," she said.

The preemie parent support group is just one of many groups available for patients and their families in nearly every hospital department. Groups exist for hematology patients, different types of cancer patients, and heart and heart-lung transplant and cardiology patients. There are groups for eating disorder patients, dermatology patients, spina-bifida patients, and for parents of pediatric patients and of children who have died. Regardless of the focus of the group however, the basic purpose is the same.

"We try to provide a way for people to hook up together to provide support for each other," said Steve Katz, a clinical psychologist who helps guide a head and neck surgery support group. "The individuals themselves are the helpers," he continued, recalling one girl who had lost the ability to speak due to surgery. Inspired by those in the support group who had learned to compensate, she eventually did learn to talk again. "We just provide the settings," Katz said.

When Katz and co-founders began to organize the head and neck surgery support group nearly two years ago, they held meetings in the community to identify the specific needs of its potential members. "Patients and their families felt they needed weekly meetings during which they could talk to others in similar situations, a network for members to talk to each other on the telephone or visit each other in their homes, and periodic education on topics, such as relaxation and dealing with pain, unique to their medical condition."

2-6-84

-more-

"Even after my boys came home," Peterson recalled, "they didn't develop along the same timeline as do full-term babies." Just knowing that slower development is normal, and that other parents are seeing the same delays and experiencing the same anxieties is comforting, she said.

The preemie parent group, which has about 50 members, also offers overnight housing, food, transportation, and child care to families in which the mother is giving birth. "Parents are so receptive and so grateful," Peterson said. "We don't give any medical advice, or offer any sweeping statements about what the future holds for an infant. All we want to do is let others know they're not alone."

That feeling of not being alone is key to all support groups, Katz said. Howard Larson had his larynx, tongue, pharnyx, and jaw portion removed to rid his body of cancer. His recovery was quick, he said, thanks to the full support of his family and many colleagues at work. Larson goes through myriad note pads to communicate with others, and uses a computerized voice synthesizer that enables him to "talk" on the telephone in his position as a NASA consultant.

Considered somewhat of a model to other members of the group, Larson comes to the weekly meetings, at which there are as many as 20 others, even four years after his surgery. He's always ready to share an experience or offer advice to others who may be going through what he did.

"Helping others," he wrote at a recent meeting, "is good medicine."

NOTED RADIOLOGIST RETURNS TO STANFORD

STANFORD—

Dr. Herbert L. Abrams, noted diagnostic radiologist and cardiovascular system specialist, is scheduled to join the faculty as a professor of radiology at Stanford University Medical School Sept. 1, announced Dean Dominick Purpura.

His appointment marks a return to Stanford, where Abrams held positions as director of the diagnostic radiology division from 1960-67, and instructor and professor from 1951-67. In 1967 he moved to Boston, where he is currently Philip H. Cook Professor of Radiology at Harvard Medical School, chairman of the radiology department at Brigham and Women's Hospital, and chief radiologist at the Sidney Farber Cancer Institute.

Abrams served as a visiting professor of radiology at Stanford in 1980-81, during which time he was also a Henry J. Kaiser Senior Fellow at the Center for Advanced Study in the Behaviorial Sciences, Palo Alto.

He is involved in many professional associations, including fellowships in the American Colleges of Cardiology and Radiology. Abrams has also held many editorial positions, and is currently editor-in-chief of *Cardiovascular and Interventional Radiology* and *Postgraduate Radiology*, and is on the editorial executive committee of *Investigative Radiology*.

Abrams received his M.D. in 1946 from State University of New York, Downstate Medical Center, and an honorary A.M. degree in 1968 from Harvard University. He has authored and edited a number of books, including *Angiocardiographic Interpretation in Congenital Heart Disease* (1956), *Congenital Heart Disease: An Illustrated Diagnostic Approach* (1964), *Abrams Angiography* (1983), and *Coronary Arteriography: A Practical Approach* (1983). He has also published more than 170 articles on angiography, cardiovascular physiology and disease, cardiac radiology, computed tomography, pharmacoradiology and technology assessment.

DO YOUR CREATIVE WRITING ELSEWHERE, MEDICAL CENTER OFFICIAL SAYS

STANFORD—

Stanford University Medical Center has a $28,000 graffiti problem.

That's what it cost the center to clean up its restroom walls last year, said Karl J. Hickethier, executive housekeeper.

His department, Hickethier estimates, spends an average of seven minutes a day cleaning X-rated prose and other creations of the mind in each of the center's 70 public restrooms.

Black felt pencil marks are the toughest to remove, he said. They require use of abrasive pads and hard detergents which cause damage and require a lot of wall painting.

The biggest graffiti problem seems to be in the building where some of the medical school's most creative minds work--the clinical sciences research building.

Patient rooms in the Stanford University Hospital have no graffiti problem, he said.

It used to cost more to clean up restroom graffiti in the past, Hickethier pointed out. Cleaning substances were only 50 percent effective. Now housekeepers use "Goodbye Graffiti," a cleaning product which is 90 percent effective.

Hickethier's point: this expense could be eliminated if people restrained their impulses to write on bathroom walls.

TRANSPLANT PROGRAM PRAISES INSURERS' POLICY

(Editors, news directors: The following story was sent Thursday on Business Wire to California points)

STANFORD—

A decision by Blue Shield of California to pay for heart and heart/thlung transplant operations at Stanford Medical Center was hailed Thursday (Feb. 2) as "an extremely positive step toward making the procedure more available to the public," said Lois Takaoka, the program's administrative services manager.

The action, said Takaoka, represents the first time a major insurance company has stated as a matter of policy that it would pay for heart transplants and the newer combined heart/lung procedure.

Dr. Edward Stinson, professor of cardiovascular surgeon and head of Stanford's cardiac transplant program, said he was "gratified by the company's (Blue Shield's) recognition that cardiac transplantation at Stanford is a therapeutic procedure which should be made available to the public through normal insurance channels."

Takaoka said she believed that Blue Shield's action set a precedent which other insurance companies and public funders of medical care such as Medi-Cal might hope to follow.

Takaoka noted that a majority of insurance companies currently pay for all or part of the cost of heart transplantation without stating their intentions as a matter of policy. "This should relieve some of the ambiguity and uncertainty from patients whose survival depends on a transplant operation."

Blue Shield's action, announced at a Bay Area news conference, applies only to transplants at Stanford, where Dr. Norman E. Shumway performed the first adult heart transplant operation in the United States in 1968. Since then, 291 transplants have been performed.

Stinson has stated that new programs should be initiated with caution. Both he and Shumway, now chairman of the department of cardiovascular surgery, have credited the current 75 percent two-year survival rate to exhaustive laboratory research and meticulous followup care by a large team of health care professionals.

Feb. 2, 1984 -more-

Members of the Stanford team have expressed concern that a proliferation of transplant centers will cause competition for the already scarce supply of donors. Stinson has said that the shortage of donors is the single greatest barrier to an expansion of cardiac transplantation.

Public attention has focused on patient care costs in recent years as the operation has moved further from the experimental arena. Each year, Takaoka said, federal grant money pays a decreasing proportion of the patient costs of transplantation.

By 1987, she said, all patient care funds for transplantation will be phased out for heart-only transplants, making insurance coverage vital. The transplant program is currently funded for $7.8 million for five years through 1987 by the National Heart, Lung and Blood Institute. The money is largely earmarked for cardiac transplant research with only a small portion for cover hospitalization.

Stanford now requires a $125,000 guarantee from patients to cover the cost of the operation, as well as pre- and post-transplant care. The operation costs about $10,000, which is only slightly more than the average cost of open heart surgery. Most of the costs, physicians in the progam have explained, involve cardiac care while the search for a donor is underway, as well as medications and hospitalization after surgery.

Stanford University Hospital's patient admitting service has estimated that insurance companies have provided substantial coverage for 80 percent of heart transplant patients. The federal Health Care Finance Administration currently is conducting a study to determine the feasibility of providing cardiac transplantation under the Medicare program, which recently has only paid for selected transplants in conjunction with the study.

Stanford's figures disclose that Blue Shield has denied coverage for three patients since 1981. Patients covered under a combination of Blue Shield and Blue Cross were approved 22 times and denied four other times.

CONFERENCE WILL CHART FUTURE DIRECTIONS IN RESEARCH ON MENTAL ILLNESS

STANFORD—

Some of the country's leading researchers in behavior and basic neurobiology will meet Friday and Saturday (February 3 and 4) near Stanford University Medical Center to discuss future directions for research in mental illness.

The meeting is an attempt to meld widely differing approaches to the study of brain and behavior, according to Dr. Jack Barchas, Nancy Pritzker professor of psychiatry and behavioral sciences at Stanford University School of Medicine. Barchas and Dr. John Madden, senior research associate in psychiatry and behavioral sciences, organized the meeting.

The experts assembled range from neurobiologists studying nerve pathways of learning in sea slugs to cognitive psychologists examining behavioral patterns in primates. By gathering together scientists studying different levels of the nervous system and behavior, Barchas and Madden hope to stimulate new research approaches to the problems of human mental illness.

Participants include Stanford psychology professors Albert Bandura, Richard Thompson, Gordon Bower and Jeffrey Wine, as well as biology professor Richard Scheller and neurobiology professor Carla Shatz, among others.

A keynote speech will be delivered by Dr. Steven Matthysse of Harvard Medical School, and closing addresses will be given by Dr. Seymour Kety of the National Institutes of Health, and Dr. Floyd Bloom from the Scripps Institute in La Jolla

Science and medical writers are welcome to attend the conference.

Friday sessions, beginning at 8:45 a.m., will take place at the Center for Advanced Study in the Behavioral Sciences at 202 Junipero Serra Boulevard on the Stanford campus. Saturday's sessions, beginning at 9 a.m., will be held at the Hyatt-Palo Alto Hotel at 4290 El Camino Real.

The meeting is sponsored by the Center for Advanced Study in the Behavioral Sciences, the MacArthur Foundation, the Foundations Fund for Research in Psychiatry, and by the department of psychiatry and behavioral sciences at Stanford University School of Medicine.

RESEARCHERS FIND CLUE TO ACTION OF COMMON ANTI-EPILEPSY DRUG

STANFORD—

Stanford University scientists reported Tuesday April 3 an advance toward understanding how a commonly prescribed anti-epileptic drug may act in the brain to control seizures.

Dr. Dora Goldstein, professor of pharmacology at Stanford University School of Medicine, and graduate student Barry J. Perlman found that sodium valproate, a widely used anticonvulsant, seems to achieve its antiepileptic effect by disrupting the highly organized structure of brain cell membranes.

In addition to providing new information about the biochemical action of a commonly used drug, the finding could be used to help develop better medications for controlling epilepsy, a condition that affects approximately one million individuals in the U.S., the researchers said.

Goldstein and Perlman reported on their work April 3 at the annual meeting of the Federation of American Societies for Experimental Biology in St. Louis, MO. The research was carried out with funds from the National Institutes of Health.

The researchers studied in mice the activity of sodium valproate and a group of sedative chemicals closely related to it. They found a strong correlation between the chemicals' abilities to alter cell membranes and their anticonvulsant effects: the chemicals most disruptive to the brain cell membranes were also the most powerful in controlling seizures.

"These results provide strong evidence suggesting that sodium valproate and other short chain fatty acids might exert some of their anticonvulsant effects by disordering brain cell membranes," the researchers said.

Sodium valproate is a molecule in a family of lipid chemicals known as short chain fatty acids. These drugs have been shown to have anesthetic effects in animals, although how they produce their actions has been an unknown.

Used in Europe since the early 1970s, sodium valproate was approved in the U.S. as an anti-epileptic in 1978, and is quite effective against different forms of epilepsy, Goldstein and Perlman noted. However, like all other anti-epileptic medications, it does not work for every patient and it has some side effects such as liver toxicity in in rare cases, they said.

Drug companies and medical researchers would like to design drugs that can help more people while producing fewer side effects, the researchers noted. However, in order to design more effective drugs it is helpful to understand at the biochemical level how available medications produce their desired effects in the body.

Goldstein and Perlman administered several different short chain fatty acids to mice that had been given a seizure-inducing drug—a standard method used in testing strength of anticonvulsant agents. They compared the relative anticonvulsant potency of these different lipids and determined the actual brain levels of drug achieved at the time of seizure protection. All the fatty acids displayed anticonvulsant ability of differing strengths, the scientists reported.

The chemicals' anticonvulsant potencies were then correlated with their actions in disordering cell membranes. Just as a hard cube of butter can soften when warmed, these chemicals cause cell membranes to fluidize and become less rigid.

To find the degree to which each chemical disordered cell membranes, the researchers used a technique called fluorescence polarization. In this method, dye molecules were inserted into the membranes of brain cells taken from the drug-treated mice.

Analysis of fluorescent light emitted from the dye molecules in the membranes gave a measure of their freedom to rotate. Stiff, tightly ordered membranes held the dye molecules in place, whereas the dye molecules could twist in the fluid, disordered membranes.

Since the most powerful anticonvulsants were also the most effective membrane-disordering agents, the researchers suggested that the membrane-jumbling effects of the short chain fatty acids may be the key to how these chemicals protect against seizures. But a further question to be answered, they added, is how disordering of brain cell membranes can prevent epileptic seizures from occurring.

FOR IMMEDIATE RELEASE

PHYSICIANS PREDICT OUTLOOK FOR PATIENT SERVICES

STANFORD—

Four prominent physicians agreed Tuesday night (March 27) that health services are being reduced by economic pressures but that the quality of care for patients need not necessarily decline.

"Things that you are used to getting are going to change," said Dr. James F. Silverman, chief of staff at Stanford University Hospital (SUH). "Services will become more spartan."

Silverman moderated the first of three public Progress in Medicine Lectures on "Health Care in Crisis," sponsored by the Stanford Medical Center. He was joined in the panel discussion by Dr. Melvin C. Britton, an internal medicine physician at Palo Alto Medical Foundation; Dr. Halsted R. Holman, professor of medicine at Stanford; and Dr. Michael Jacobs, director of the Stanford Medical Group, a group practice operating within the university's Faculty Practice Program.

Entitled "Cost Controls: What Does it Mean to You and Your Doctor," the first of the three Tuesday lectures focused on how rising health care costs have resulted in a variety of cost containment measures which are affecting patient services.

"We all try to ration care without losing quality," said Silverman, a diagnostic radiologist. "That's where you see the system is right now."

However, David Sakai, SUH's director of finance and one of about 150 audience members, said during a question and answer period Tuesday that he perceives many of the changes noted by the panelists as temporary.

"We're talking about a cycle." Access to care, he said, may be somewhat restricted, but he predicted it constraints may ease. Sakai pointed to market pressures which could be driven by a consumer demand for more choice than prospective payment plans allow.

Examples of such plans are health maintenance organizations (HMOs), such as Kaiser or TakeCare, and prospective payment plans, such as Blue Cross' new Prudent Buyer plan. In the public sector, MediCal is now offering services on a contract basis, paying less than full cost for the patients it supports.

Since they will not be fully reimbursed or have a financial incentive to increase services, health care organizations might feel pressured to cut back on services, which Holman said can sometimes be a blessing in disguise for patients.

"Elimination of redundant or unnecessary practices means that the doctor has to begin to think about the usefulness of the tests and treatments we use. Do they really provide benefits to the doctor in the decision-making or the patient in the outcome.

"Many of the practices which we consider good in professional terms, which we teach and which we use, can be shown to be redundant or unneccessary," added Holman, who co-founded Mid-Peninsula Health Services, Inc., a prototype patient-involved, health care delivery system intended to reduce costs."

As an example, Britton, who directs the TakeCare health maintenance organization at Palo Alto Clinic, said some recent studies have shown "the actual outcomes for patients with pulmonary edema in intensive care units are not better than in general hospital wards or other units." He said physicians and the public will need to question intuitive notions that high technology treatments are automatically better.

3-28-84

-more-

"Those intuitive notions may absolutely be proven false. (We must) answer the question of tertiary care (high technology care for extremely sick individuals) by asking, 'who really needs it?' "

Jacobs said cost-saving payment plans, such as HMOs, may run counter to patient expectations.

"Often patients will come to Stanford expecting that they're going to get a very, very, thorough comprehensive evaluation without a whole lot of sense of being rushed through the system. But that's just not going to be financially feasible once we start feeling the impact of an HMO" where a predetermined amount has been paid.

"We cannot," Jacobs continued, "take an hour or two hours to do a lot of expensive tests. I have a feeling that patient expectations are going to have to adjust to this.

"Secondly, will there be a price paid in terms of misdiagnosis because we are moving faster and we are not using the available resources that exist here at Stanford.

"...Time will tell us. In the meantime, I feel we really have very formidable challenges ahead of us. I think these challenges are quite exciting."

On the other hand, both Jacobs and Britton agreed that some procedures are performed because the patient expects certain things, which may not be necessary.

"Ask your doctor," said Britton, "'Why are you taking that X-ray?'" Britton said when he's asked that, he will stop and think whether he's ordering the test because it is truly necessary or because patients simply expect to have a wide variety of tests performed.

"It never hurts to ask," he added.

"I think a lot of what we do with taking care of patients is responding to what we perceive the patient's expectations are," said Jacobs. "And I think in many instances I'm quite aware of a lot of hocus pocus that I do with an ophthalmoscope looking in somebody's eyes, and a stethescope on sombedoy's chest that I listened to a year ago. If the person had no symptoms" it's not likely to change that quickly.

Holman called for what he called "appropriate technology assessment.

"Potentially we could develop the means of more wise use of our resources," he said.

"It isn't beyond our capabilities to design systems that will begin to address these escalating costs and provide alternate forms of health care that in one way or another can be judged either superior to or equal to or more satisfying than the conventional" approaches.

Silverman noted that more than 10 percent of our gross national product is spent on health care, $322 billion in 1982. In recent years the majority of the increase can be attributed to rising prices of goods and services, he said.

The free public lecture series continues at 7:30 p.m. on the next two Tuesdays in Sherman Fairchild Auditorium at the Medical Center. On April 3, the topic is "The Practice of Medicine: Does Competition Compromise Quality?" moderated by Dr. Michael Eliastam, director of emergency services at SUH. On April 10, Dr. Thomas A. Gonda, chairman of the Department of Psychiatry, will moderate a physician panel discussion on "Medical Decision Making: Is It Being Taken Away From You and Your Doctor?"

RESEARCHERS USE NEW DEVICE TO STUDY BEDWETTING IN CHILDREN

STANFORD—

Researchers at Stanford University School of Medicine are investigating new ways to diagnose and treat bedwetting, a problem that dampens the lives of adults as well as children.

The new techniques determine whether bedwetting flows primarily from a physiological problem or an emotional one. Physicians can then institute the most appropriate therapy, said Dr. Christos Constantinou, associate professor of surgery.

Bedwetters can be broadly divided into two types, depending on whether their bladders are "stable" or "unstable," Constantinou explained. A person with a stable bladder has the capacity to control the contractions that cause urination to occur, but may not exercise that control for emotional reasons, he said.

In contrast, an unstable bladder's contractions cannot be voluntarily controlled. A bedwetter with this type of bladder has a physiological problem, Constantinou noted.

With a special diagnostic system that measures bladder pressure and muscle contraction, Stanford researchers can now perform simple tests to determine whether a bedwetter's bladder is stable or unstable, Constantinou said.

The diagnostic tests are performed with a microcomputer-based device called the Endotek Uroflow System. The unit was donated to Stanford by Endotek president Michael Ditmore, a Stanford business school alumnus, Constantinou said. Endotek, a Santa Barbara-based company, designed the equipment in collaboration with the urology division at Stanford, he added.

The new equipment is currently being used to diagnose bladder problems in children with bedwetting problems, Constantinou said.

Enuresis, or bedwetting, may affect as many as 10 to 15 percent of children over five years of age; half of these children will lose their bedwetting tendencies by the age of 12, Constantinou said.

In a study based at Children's Hospital at Stanford, Constantinou and Dr. Gregory Fritz, assistant professor of psychiatry, are examining the effectiveness of a drug called imipramine in reducing bedwetting behavior. The drug treatment is being tested in children hospitalized for a variety of behavioral problems, Constantinou said.

3-28-84 -more-

Bedwetting in children with emotional problems is a complex condition to treat, Constantinou explained. Even if the bladder is stable, or normal, a child may have a psychological barrier against learning more appropriate behavior, he said.

One form of therapy for enuretic children depends on a special mattress that is activated to ring bells and flash lights when the sleeping child urinates, Constantinou explained. But drug therapy might be more humane, he suggested, if it is quicker, more effective, and less disturbing for the child.

In addition, for children whose bedwetting is caused by an unstable bladder, a drug would be the most appropriate form of treatment, he said.

Imipramine, sometimes used as an anti-depressant medication, acts by blocking acetylcholine, a chemical signal used by nerve cells. It seems to increase the bladder's resistance to contraction, Constantinou said.

The Uroflow device measures bladder pressure—a sign of urination—and contraction of muscles around the anus—a measure of the person's attempt to hold back urine flow. A person with a stable bladder is relaxed during urination whereas a person with an unstable bladder exhibits muscular contraction whenever urination occurs, Constantinou explained.

The device can also be used to prevent minor urination problems from worsening, Constantinou observed. "Some people empty their bladders by starting and stopping many times. This can produce obstructions and other problems in urination," he said.

To aid this type of problem, the unit incorporates a biofeedback system that can train an individual to urinate in a continuous stream, Constantinou explained. The computer couples a musical tone to urine flow, and by listening for the feedback tone, a person with a normal bladder can learn to empty it with a single gradual flow, he explained.

MIS PROGRAM ATTRACTS SUPPORT FROM DIVERSE SOURCES

Editors: Photos of Shortliffe available on request.

STANFORD—

Members of the corporate world have found an interest in common with traditional sources of support, such as government and philanthropy, in Stanford University's new interdepartmental graduate degree program in Medical Information Sciences (MIS).

The program, directed by Dr. Edward Shortliffe, an assistant professor of medicine and computer science, was approved by the university's faculty senate in 1982 to provide a structured curriculum which combines medical and computer science training.

Students may be physicians who wish to enhance their knowledge of computer science or of formal medical decision making. Others may be computer science majors with a background in biology or a related field who wish to make a commitment to MIS.

The melding has already led to such innovations as helping doctors diagnose patients' ills by using computers to analyze their symptoms and medical history.

Groups that have pledged support to the program over the past few months, totaling about $516,000 for its first official year (1983-84), are: Hewlett-Packard (HP); the Josiah Macy, Jr. Foundation; The Educational Foundation of America (EFA); Corning Glass; and the National Library of Medicine (NLM) of the National Institutes of Health.

Dean Morton, executive vice president of HP, explained: "With constantly improving performance and reductions in computer costs, it's now possible to view the eventual use of economic desk-top systems as feasible throughout the medical community. Ultimately, of course, HP would like to provide such systems." Morton also serves as a hospital board member at Stanford.

3-27-84

-more-

HP has supported the training program with a large equipment grant totaling more than $300,000, as well as a cash gift.

Corning, meanwhile, has pledged support for three years to the research aspects of Shortliffe's work. "Corning is interested in the use of computer techniques for the management of clinical laboratory data," he said.

The two philanthropic foundations, EFA and Macy, have always been interested in supporting innovative approaches in medical education at Stanford and elsewhere, Shortliffe noted.

NLM selected five out of a pool of American programs to support with five-year grants for postdoctoral trainees in MIS. The federal grant to Stanford was approved by the Board of Regents, and is likely to be funded starting July 1, 1984.

"These recent grants break new ground in recognizing the importance of this dual discipline which is still in its infancy," said Shortliffe, who is also co-director of SUMEX-AIM (a Stanford-based, nationally shared resource for artificial intelligence research in medicine and biology).

"Our MIS program is somewhat unique in that there are a core curriculum and degree requirements," Shortliffe added. "Also, it is oriented toward persons interested in research and an academic environment."

Ph.D. and two-year M.S. routes are joined by a limited one year master's program, intended as supplemental training for established researchers.

The past pattern, Shortliffe said, was for M.D.s interested in MIS to get a Ph.D. in computer science. But this resulted in a "highly theoretical" computer orientation often failing to relate effectively to the clinical environment.

Also, "Without the specialized degrees which this program offers, students who combined the two disciplines on an informal basis often were enticed into other areas of the rapidly expanding computer science field," Shortliffe said.

***HOLD FOR RELEASE. The following embargoed for release for AMs publications, Thursday, March 29 to coincide with publication in the** New England Journal of Medicine*

ALCOHOL'S ROLE IN HEART ATTACK PREVENTION QUESTIONED

STANFORD—

If moderate alcohol consumption lowers the risk of heart attack, it isn't because it raises the level of good cholesterol in the blood, according to a Stanford researcher.

Several recent studies have indicated that alcohol consumption can increase the level of so-called "good" cholesterol, the high-density lipoproteins (HDL). But Dr. William Haskell, clinical associate professor of medicine, said that the results are deceiving.

"If alcohol is helpful at reducing the risk of heart attack—and we have evidence from other studies that it might be—it probably is not because it increases HDL levels," said Haskell, who published results of a study Thursday (March 29) in the ***New England Journal of Medicine***.

Haskell's study has shown that alcohol affects two separate components of HDL differently.

Other recent studies have shown that one of these components, less dense HDL2, appears to be the substance which when found in quantity reduces heart attack risk. HDL2 particles, Haskell said, act as scavengers, constantly bombarding artery walls, removing dangerous fat particles and transporting them to the liver where they are removed from the body.

The level of denser HDL3, the other component, appears to have no effect on heart attack risk.

What the work of Haskell and his colleagues has shown is that moderate drinking raises the level of the inert HDL3, but leaves the more important HDL2 levels unchanged.

"Most lab tests don't differentiate between these two types of HDL. So it is a natural assumption that when a patient finds his overall level is rising, he might believe his heart attack risk is going down. Our study shows that this—much to the dismay of moderate drinkers like myself—is untrue," he explained.

Haskell said his study appears to refute simple correlations, such as one study which appeared to show that three beers a day would have the same HDL cholesterol-raising effect as endurance exercise.

Haskell is quick to point out that moderate alcohol may be beneficial at reducing heart attack risk, "but if so, it isn't because it raises HDL2. We just don't know enough yet to be able to say why alcohol in moderate quantities might be beneficial, although it is becoming clear from other studies that moderate drinkers tend to have fewer heart attacks than non-drinkers."

(HDL is sometimes confused with low-density lipoproteins (LDL), the "bad" cholesterol which increases heart attack risk by causing the blood vessels to clog up. High HDL is good, while high LDL is considered potentially dangerous.)

3-27-84

-more-

The recent study, besides offering useful health information, is important because of the insight it offers into the differing response to alcohol of the two forms. However, it is still not known how alcohol affects HDL levels in the blood, Haskell said.

"What we discovered," said Haskell, "are wheels within wheels. We once believed that all cholesterol was the same. Later we found the distinction between HDL and LDL, and then we learned that there are at least two types of HDL. In this study we learned about the relationship between alcohol and these two types of HDL."

Haskell's study involved 24 healthy men aged 30 to 60 who were divided equally between treatment and control groups. The treatment group abstained from alcohol for six weeks. During the next five weeks, that group returned to what had been their normal level of moderate alcohol use.

The reserchers found that HDL2 appeared not to be lowered or raised whether the patient quit or resumed drinking.

Other studies, said Haskell, indicate that vigorous exercise, such as running, significantly increased HDL2 while decreasing HDL3.

The NEJM article, "The Effect of Cessation and Resumption of Moderate Alcohol Intake on Serum High-Density Lipoprotein Subfractions," was also written by Carlos Camargo Jr., a former Stanford student; Paul T. Williams, a biostatistician with the Stanford Heart Disease Program (SHDPP); Karen M. Vranizan, SHDPP programer; Ronald M. Krauss, staff medical scientist, and Frank T. Lindgren, biophysicist, both from the Donner Laboratory of Medical Physics at the University of California-Berkeley; and Peter D. Wood, deputy director of the SHDPP.

The study ended with a caution that "alcohol may supplement exercise undertaken to promote cardiovascular health but should not be considered as an alternative.

"Clearly, the detrimental effects of even moderate alcohol (liver disease, traffic accidents, etc.) over extended periods must be weighed against any 'protective' effects against coronary heart disease."

PUBLIC LECTURES ON WOMEN AND HEALTH

STANFORD—

A Friday noon lecture series on women and health will be presented this spring by the division of family of medicine at Stanford Medical School.

Open to the public free of charge, the scheduled lectures are:

- April 6: "Turning Around," a film about sexism in medical school by Maureen Longworth, UCSF medical student;
- April 13: "Women, Leadership, and Madness," with Barbara Stephens, Ph.D., psychologist and medical educator, director of the Institute for Education in Health Sciences;
- April 20: "DES: The Lifeboat that Sank," with Pat Cody, M.S., health educator, economist, one of the founders of DES Action;
- April 27: "Rethinking the Knowledge Base for Health Education and Promotion Programs for Women: a Critique," with Sheryl Rusek, M.P.H., Ph.D., adjunct associate professor of sociology, UCSF, and co-director of the Women, Health and Healing Project;
- May 4: "Sexism and Health Care Policy," Donna Ambrogi, managing attorney, Bay Area Law Center on Long Term Care and coordinator, Care Giver Task Force;
- May 11: "Gender, Language and Medicine," with Candace West, Ph.D., assistant professor of sociology, UCSC, teacher of Sexual Politics of Medicine, author of *Routine Complications: Trouble with Talk Between Doctors and Patients*;
- May 18: "Mixed Messages for Women: Smoking and Cigarette Advertising," with Virginia Ernster, Ph.D., associate professor of epidemiology, UCSF;
- May 25: "Women, Science and Society: Issues in Reproduction and Contraception in Early Twentieth Century," with Adele Clarke, M.A., doctoral candidate in sociology, UCSF, faculty member at Sonoma State University;
- June 1: "Legal Implications of Sexism in Medical Employment," with Mary Dunlap, civil rights attorney and law teacher.

A discussion group with case presentations will be held for enrolled participants following each lecture from 1:15 to 2 p.m. with the speaker. Also participating will be Marita Grudzen, program manager of the SUMC Women's Health Care Project; Jeanne DeJoseph, C.N.M., Ph.D.; and Judith Martin, M.D. from the Division of Family Medicine.

The lectures will be held from noon to 1 p.m. in Room M114 of the medical school. For further information, call (415) 497-7066 weekdays.

FOR IMMEDIATE RELEASE

COMMITTEE INVESTIGATES MISCONDUCT CHARGES INVOLVING PROFESSOR

STANFORD—

A committee of the Stanford University School of Medicine is investigating allegations of academic misconduct involving a faculty member, a University official confirmed Thursday (March 22).

The internal review of charges is being conducted by the Medical School's Committee on Ethical Scientific Performance in accordance with procedures established to deal with such allegations, said Dean Dominick P. Purpura, committee chairman.

He made the statement in response to a press report in Thursday's edition of the *San Jose Mercury News*. The report said the faculty member under investigation was Dr. Kenneth Melmon, professor and chairman of the Department of Medicine.

Earlier Purpura had declined to name the faculty member involved or comment on the allegations and merits of the case "because committee inquiries are confidential, according to university policy," he said.

But in a statement issued late Wednesday in response to Mercury inquiries, Melmon's attorney and Stanford law professor Jack H. Friedenthal discussed the allegations against Melmon and stressed "there is no justification for any university sanctions against him whatsoever."

Melmon in an interview quoted in the Mercury, said he had committed an honest mistake and he had submitted evidence to the medical school's ethics committee in hopes of proving his innocence.

The committee's investigation was begun in mid-February when an editor of a medical text, Goodman and Gilman's *The Pharmacological Basis of Therapeutics* published by MacMillan Publishing Co., complained that Melmon had incorporated material without permission into a chapter he had authored for another text, according to Friedenthal. The book in which Melmon's chapter appears is the *Textbook of Endocrinology*, Sixth Ed., edited by the late Robert H. Williams and published by W. B. Saunders. Melmon also has served as an associate editor of the Goodman and Gilman textbook.

Friedenthal in his statement confirmed "the materials taken were incorporated nearly verbatim with some minor editing for style." But he added, "Dr. Melmon has been able to locate files that show he always intended to use the Goodman and Gilman materials with permission and attribution."

In response to questions, Friedenthal said unfortunately, Melmon may not have been as clear as he thought. Somewhere in the process there was a failure on the publishing side to do what he intended.

Friedenthal said Melmon is sorry for what has occurred. "He has sent a letter to the aggrieved people involved with the Goodman and Gilman book and has offered to do whatever he can to avoid future harm," he said.

The charges, Purpura said, were being investigated under the university policy set in a January 31, 1983 memorandum by Albert H. Hastorf, vice president and provost, outlining procedures for handling allegations of academic misconduct.

It is the purpose of the policy, Purpura said, to make timely responses to allegations involving faculty misconduct to protect the interests of all concerned.

-more-

The committee will forward its confidential findings to Stanford University President Donald Kennedy within a few weeks, he said. The president will then determine whether there is a basis for bringing charges in accordance with the procedures detailed in Stanford's long-standing "Statement on Faculty Discipline."

Melmon, a clinical pharmacologist, is a Stanford undergraduate, with a medical degree from the University of California in San Francisco. He came to Stanford seven years ago from the University of California in San Francisco where he was professor of medicine. The 49-year-old professor holds the Bloomfield endowed chair in the department of medicine and a joint appointment in the Department of Pharmacology. In addition he is physician-in-chief of the medical service at Stanford University Hospital.

—30—

Following is the text of Friedenthal's statement released to the press:

1. Some four years ago, Dr. Kenneth Melmon, chairman of the Department of Medicine at the Stanford School of Medicine, incorporated some materials from the manuscript of a then forthcoming Sixth Edition of a medical text, Goodman and Gilman on Pharmacology, into a chapter that Dr. Melmon was preparing for the Sixth Edition of the text, Williams on Endocrinology.

2. The materials taken were incorporated nearly verbatim with some minor editing for style because Dr. Melmon intended that anyone reading the materials would be fully aware that they came from Goodman and Gilman.

3. Dr. Melmon incorporated the materials at the urging of the editor of the Williams book, and refused to do so until he (Dr. Melmon) was informed by the editor that permission to do so had ben received from those in charge of Goodman and Gilman.

4. Dr. Melmon also made notations on his original manuscript regarding the need for attribution to Gilman and Goodman at points where materials from the latter were incorporated.

5. Four years later, after both books had long since been published, Dr. Melmon was stunned when he was informed by an editor of Goodman and Gilman that permission had never, in fact, been sought or given, and that the actual attributions were insufficient.

6. Despite the passage of time, Dr. Melmon has been able to locate files of materials that show that he always intended to use Goodman and Gilman materials only with permission and attribution. Unfortunately, the editor of the Williams book has died and Dr. Melmon has been informed that his files regarding the book have been discarded.

7. Although the matter is unfortunate, it really isn't all that important for the following reasons:

a. This was not the appropriation of someone's original research or the falsification of data that would enhance Dr. Melmon's career or prestige. Dr. Melmon had absolutely nothing to gain by the improper use of the materials from the Goodman and Gilman book. His was only one chapter of many in the Williams book. The book is basically for the use of students and practicing physicians and provides no academic credit for chapter authors.

b. The two books do not compete with one another. It is hard to think of how anyone suffered because ten or fifteen pages from one were used in the other. It took years for the matter even to come to light.

c. Dr. Melmon's intentions were proper. Without a showing that Dr. Melmon intended to commit fraud, there is no justification for any university sanctions against him whatsoever.

8. The matter is now in the hands of a standing investigative committee. Ultimately, the question of whether to go any further will be made by President Kennedy.

SCIENTISTS IDENTIFY FIRST DNA SEQUENCE

CONTROLLING GENE EXPRESSION IN ORGANELLE DNA

STANFORD—

Scientists at Stanford University have identified a DNA segment in the cell's miniature power plant—the mitochondrion—which plays a key role in regulating energy production inside cells.

Mitochondria, the energy-suppliers in all animal cells, contain their own strands of DNA—the genetic material of living things—and can duplicate themselves inside cells.

The segment of genetic material found by the Stanford researchers lies in the mitochondrion's own DNA molecule. It probably helps control the production of cellular machinery required to generate energy and also the mitochondrion's ability to replicate itself, the researchers said.

This is the first information on DNA sequences that control expression of genetic material in any organelle from cells of higher organisms, said Dr. David Clayton, professor of pathology at Stanford University School of Medicine.

Organelles are the specialized compartments that carry out vital functions inside the cells of plants and animals.

Clayton and David Chang, a Stanford medical student, carried out the research, published in the March issue of the journal *Cell*.

The sequence of DNA found by Clayton and Chang is called a promoter. Enzymes in the cell must attach to a promoter in order to decode DNA's message, just as a zipper tag needs to fit into a zipper latch in order to draw the fastener closed.

Promoters are the key to understanding how DNA's message is decoded inside cells, Clayton explained. They are the master stretches of DNA that control whether or not particular genes are expressed. Clayton hopes that identification of the mitochondrial DNA control sequences will shed light on the workings of these miniscule organelles.

3-20-84

-more-

Understanding how mitochondria work is important because the fuel they provide enables cells to carry out the body's activities. Scientists are also beginning to learn that some diseases—such as Reye's syndrome—may be caused by malfunctioning mitochondria, Clayton said.

"All animals have mitochondria," he explained. "They convert what we eat into ATP, the cell's molecular fuel packet. We couldn't make use of the food we eat without these organelles," he added. "Our cells would starve to death."

Knowing how mitochondria work also could provide insight into certain types of cancers, Clayton noted. In leukemia, the mitochondrial DNA forms a double loop called a dimer, he said. The significance of this twin DNA molecule is not known, he said, adding that "the only way to find out is to first learn more about the normal mitochondrial DNA molecule."

The numbers of mitochondria vary in cells, depending on the cells' energy needs. Just as an interstate truck needs a big engine while a compact car uses only a small motor, the hard-working cells of heart muscle are packed with energy-generating mitochondria, while relatively lazy skin cells contain only a few of the organelles.

The mitochondrial population inside each cell is thought to be controlled jointly by the nucleus, where most of the cell's DNA resides, and by the mitochondrial DNA, Clayton explained. Although mitochondria can proliferate independently inside their host cells, duplication probably begins only when an OK signal comes from the cell nucleus, he suggested.

The segment of mitochondrial DNA that Clayton and Chang found is probably part of the site at which signal molecules from the nucleus deliver their message, Clayton said.

Now that the DNA segment has been isolated, genetic engineering techniques will enable the researchers to study just how signals from the cell nucleus interact with the mitochondrial DNA to tell it when to reproduce itself, he predicted.

Studies of the mitochondrial DNA promoter should also reveal how the organelle and nucleus interact to control synthesis of the proteins involved in making energy-rich ATP, Clayton said.

The researchers already have made an interesting discovery, Clayton reported. They found that the promoter sequence on mitochondrial DNA varies more than analogous sites that control expression of DNA in the nucleus. Although nuclear DNA promoters are similar in species as diverse as human and fruit flies, the control sequences on mitochondrial DNA vary even among mammalian species.

The research was funded by grants from the National Institutes of Health and from the American Cancer Society.

STUDIES OF CELL SHAPE MAY PROVIDE CLUES TO CANCEROUS GROWTH

STANFORD—

Abnormalities of the protein structure that controls cell shape may contribute to malignant disease, say researchers at Stanford University School of Medicine.

Dr. Larry Kedes, professor of medicine, and his colleagues are studying a protein called actin, one of the building blocks of the miniature cables and beams that make up the cell's scaffolding, called the "cytoskeleton."

"There is a school of thought suggesting that cell shape controls normal cell growth," explained Kedes. It holds that a disturbance in cell shape—in the natural ruffles and projections formed by the cytoskeleton—shuts down some sort of cell-to-cell communication normally operating to keep cell growth in check, Kedes said. Recently, certain types of cancerous cells have been discovered with abnormal actin molecules in their cytoskeletons, he added.

Kedes and his coworkers have developed a way to test whether the abnormal actin protein in malignant cells is a factor in causing the cells to turn cancerous.

Kedes' system for examining actin in mouse cells in tissue culture was described in the March issue of the journal *Cell*.

His colleagues at the Palo Alto Veterans Administration Medical Center are Drs. Peter Gunning and Phyllis Ponte. Other collaborators are Dr. John Leavitt at the Linus Pauling Institute in Palo Alto, and Drs. Robert Hickey and Arthur Skoultchi of the Albert Einstein College of Medicine.

Using recombinant DNA techniques, the scientists succeeded in placing the gene coding for a human type of actin into mouse cells. The mouse cells absorbed the human gene, adding it to their DNA, and began producing the human actin. The mouse cells then incorporated the human protein into their cytoskeletons right along with the normal mouse cytoskeletal actin protein.

-more-

The type of actin they produced in the mouse cells was of a form normally found predominantly in human heart muscle cells, not actin found in cytoskeleton, Kedes said. Yet the mouse cells did not seem to notice the difference. They built their skeletons using the unusual actin molecules, and the cytoskeletons seemed normal.

"By introducing the cardiac actin gene into mouse cells, we were able to remodel the cell architecture, and look at the results," Kedes said.

Now, the researchers will make changes in the human actin gene, and insert it into the mouse cells, which will then produce abnormal actin. They can then monitor what happens to mouse cells that build their cytoskeletons using the altered actin molecule. In particular, they can watch for changes in cell shape and growth pattern that could signal that the abnormal actin has transformed the cells to the malignant state.

Malignant cells have unusual shapes and behave differently from normal cells in tissue culture, Kedes explained. Normal cells have ruffles and projections on their surfaces. When these extensions touch one another, neighboring cells stop growing, forming a neat layer one cell thick.

In contrast, malignant cells lose the finger-like projections, rounding up into balls that grow all over each other in a dense mass.

It's not yet known what goes awry in such cancerous growth, said Kedes, although one suggestion is that some form of communication shuts down. Normal communication might depend on a signal generated at the cell surface when the projections of neighboring cells touch, he said. In normal cells, this signal might curb DNA synthesis and cell division. But in malignancy, this control of DNA replication might not be triggered by cell surface touching, Kedes suggested.

Studying the human actin gene inserted into mouse cells may allow the researchers to investigate other basic questions such as how cells control which genes are expressed in their DNA. It also could help reveal how cells control the assembly of internal structures from available protein parts, Kedes said.

The form of actin used in the research is normally produced in muscle cells, and it is an important component of the contracting filaments in muscle, Kedes said. For this reason, he expects that the genetically engineered mouse cells may also help shed light on regulation of genes in muscle cells. This could be of clinical significance in understanding diseases such as muscular dystrophy, Kedes noted.

The research is supported by grants from the National Institutes of Health, the Veterans Administration, and the Muscular Dystrophy Association.

RAINE TO GIVE LECTURE ON MULTIPLE SCLEROSIS

STANFORD—

Dr. Cedric Raine, professor of neuropathology at the Albert Einstein College of Medicine, will give the eighth annual George A. Zimmermann Lecture at Stanford University Medical Center Friday, March 30.

His public talk, "What's Special About Multiple Sclerosis," is scheduled for 5 p.m. in Room M106 of the medical school.

Raine's research has focused on diseases caused by breakdown of the outer layer of a nerve cell, called the myelin sheath. He was one of the first to carry out studies in the central nervous system of this breakdown, when caused by immune disorders. One disease caused by such "demyelination" is multiple sclerosis (MS).

Raine received his Ph.D. at the University of Newcastle Upon Tyne, England, and worked at the Medical Research Council Research Unit in Newcastle until 1968, when he joined the Albert Einstein College of Medicine. He is chief editor of the *Journal of Immunology* and associate editor of the *Journal of Neurocytology* and *Journal of Neurological Sciences*.

The Zimmermann Lectureship was established by the Department of Neurology in 1977. It was part of a gift for research and treatment of MS at Stanford, from the late George A. Zimmermann, a long-time San Francisco businessman.

LECTURE SERIES SLATED AT STANFORD UNIVERISTY MEDICAL CENTER

STANFORD—

"Health Care in Crisis: Questions of Costs and Quality" is the topic of Stanford University Medical Center's spring Progress in Medicine lecture series scheduled for March 27, April 3, and April 10, 1984.

The lectures, open and free to the community, will be held in Sherman Fairchild Auditorium beginning at 7:30 p.m.

"Pressures to control rising health costs have brought about changes that affect the public, physicians and hospitals. The practice of medicine is dramatically changing. The focus of the lectures is to provide information and enhance the public debate about these issues," the program states.

The first lecture of the series on March 27 will focus on "Cost Controls: What Does It Mean to You and Your Doctor?" Moderating the panel discussion will be Dr. James Silverman, chief of staff at Stanford University Hospital (SUH). Panelists include Dr. Melvin Britton, clinical associate professor in the department of medicine and director of TAKECARE, a health maintenance organization offered at the Palo Alto Medical Foundation, and Dr. Halsted Holman, professor in the department of medicine and co-founder of Mid Peninsula Health Services, Inc.

"The Practice of Medicine: Does Competition Compromise Quality?" is the focus of the second lecture of the series on April 3. Dr. Michael Eliastam, assistant professor in the department of surgery and medicine and director of SUH's emergency services, will moderate the panel, which will include Sheldon King, executive director of SUH, John Aryd, president of San Jose Health Center, and Art Young, corporate benefits manager at Hewlett-Packard.

The last of the series on April 10 will address "Medical Decision Making: Is It Being Taken Away From You and Your Doctor?" Dr. Thomas Gonda, chairman of the department of psychiatry and of the medical center ethics committee will moderate the discussion. Panelists include Dr. Keith marton, assistant professor in the department of medicine, and Dr. Thomas Raffin, assistant professor and assistant chief in the department of medicine.

Seating is limited for the lectures. For information and registration, call the Office of Public Events, (415) 497-6389.

SUBSTANCE SHOWS PROMISE FOR TESTING IN AIDS PATIENTS

STANFORD—

A genetically engineered form of a natural protein can boost the disease-fighting capacity of cells from patients with acquired immunodeficiency syndrome (AIDS), report scientists at Stanford University School of Medicine and Cetus Corporation.

In a study to be published in an upcoming issue of the medical journal *Lancet*, a substance called interleukin-2 (IL-2) reversed some deficiencies of immune system cells taken from the blood of AIDS patients.

However, the researchers stressed that their *in vitro* (test tube) study does not mean that IL-2 will cure AIDS, a devastating syndrome in which the immune system fails to defend the body against infection and certain cancers.

"We cannot predict what will happen when this substance is tested in human beings," cautioned Dr. Edgar Engleman, assistant professor of pathology and medicine at Stanford, who led the study. "There is no guarantee that interleukin-2 will be effective in treating AIDS," he said. "We are encouraged, but must await results of clinical trials before we can determine its usefulness in patients."

Engleman said that researchers at the University of California in San Francisco are currently planning clinical trials to assess the protein's ability to help restore immune function in patients with AIDS.

The study was performed by Dr. Jeffrey Lifson and Claudia Benike in Engleman's laboratory at Stanford. The genetically engineered IL-2 was produced by a team of scientists led by David Mark and Kirston Koths at Cetus in Emeryville, California. Engleman has a consulting relationship with the company.

The researchers studied IL-2 because it is known to be involved in activating the immune system, the body's defense network against infection and cancers.

The immune system of patients with AIDS is so weak that their bodies cannot fight off infections and cancers that are routinely squelched in healthy individuals.

No one knows precisely what causes the immune system to close down in AIDS, Engleman said, although many researchers suspect a virus may be involved.

IL-2 probably will not prevent or reverse that initial shutdown, Engleman said. But it may help bolster the immune system by compensating for functions lost as a result of that shutdown.

3-13-84 -more-

If IL-2 proves useful in treating AIDS, it would be a positive step toward dealing with the disease, Engleman said, although it is possible that patients would have to be placed on a longterm treatment program, like diabetic patients who require insulin, he noted.

IL-2 is a signal molecule used by cells of the immune system called lymphocytes. Lymphocytes come in two main types: B-cells and T-cells.

B-cells produce antibodies, protein molecules that fight disease. T-cells regulate the actions of B-cells and they can also directly destroy foreign or abnormal cells in the body.

One type of T-cell, called a helper, turns on the immune system when it detects infected or cancerous cells. Another T-cell, called a suppressor, turns the immune system off. A balance between helpers and suppressors keeps the immune system finely tuned, Engleman explained.

Helper and suppressor cells use signal molecules like IL-2 to keep the immune system running smoothly. IL-2, produced by helpers, stimulates T-cells to grow, divide and assault infected or cancerous cells in the body, Engleman said.

In patients with AIDS, the population of helper T-cells is profoundly reduced, and the few residual helper T-cells don't work well.

The researchers took lymphocytes from 16 patients with AIDS and from 10 normal individuals. In the laboratory, they added IL-2 and monitored the growth and activity of the immune system cells in their samples.

The most dramatic result they found was in the activity of natural killer cells, which destroy foreign cells and also kill the body's own cancerous or infected cells. Without IL-2, cells from the patients displayed very low natural killer cell activity compared to the healthy controls. But when IL-2 was added, the AIDS samples showed as much killer cell activity as the controls, the researchers reported.

The researchers found that IL-2 also stimulated growth and division of T-cells from some of the AIDS patients (6 out of 8 patients tested in one assay, and 4 out of 8 patients using a different test of growth). However, T-cell proliferation did not reach levels of growth seen in normal individuals' cells, they noted.

The surprising finding was that IL-2 did not merely promote *growth* of sick T-cells from AIDS patients. It also caused the sick T-cells to regain their ability to attack abnormal and foreign cells.

Engleman noted that it is not yet known how IL-2 increases natural killer cell activity of lymphocytes from patients with AIDS, although experiments are currently under way to answer this question.

AIDS is not the only condition IL-2 may improve, Engleman said. At other institutions, IL-2 has been tested as an anti-tumor agent in animals, with promising results. Because the substance has not yet reached clinical trials, its potential side effects in humans are unknown. However, he noted that in animals no side effects have been detected, an inducement to human tests.

The research was supported in part by grants from the National Institutes of Health and the Veterans Administration. Lifson is a recipient of a fellowship from the Damon Runyon-Walter Winchell Cancer Fund.

FOR IMMEDIATE RELEASE

NEW KIDNEY TEST NEEDS VOLUNTEERS FOR TESTING

STANFORD—

Researchers are looking for healthy volunteers to help evaluate a new test which might make earlier detection of kidney disease possible.

Dr. Mark Moran of the Stanford Medical Center's nephrology division, said the volunteers will help calibrate the new testing procedure which is believed to be a more accurate and sensitive test of kidney function.

The technique involves new chemical analysis of blood and urine to provide a very precise measure of whether the kidney is doing its job of serving as a filtration plant, removing waste materials from the blood.

Moran said the newly developed chemical analysis involves studying the molecular structure of the kidney pores as measured by the appearance in the urine of, albumin, a protein, and a sugar known as dextran after both have been filtered from the bloodf by the kidney. The albumin and dextran are injected gradually into the blood for purposes of the test, he said. Previous tests involved measuring native bodily substances in the blood, which Moran said sometimes had proven to be inadequate.

The new technique, Moran said, may enable physicians to diagnose kidney disease at a much earlier stage than before.

"It is hoped that early detection of kidney disease by allowing timely treatment, may prevent the progression to kidney failure," Moran said.

"Ultimately," he continued, "the number of patients requiring dialysis (artifical kidney) treatment and transplants may be decreased if dysfunction can be discovered in time to begin treatment."

The test, he said, is of scientific value because it "will help researchers understand the way in which kidney function changes from normal when kidney disease develops," Moran added.

So far, Stanford doctors have tested the technique in more than 500 patients suffering from kidney disease. But now, he said, researchers need more healthy volunters to determine precisely the normal level of kidney function as defined by this test.

Volunteers should be free of known kidney disease and have normal blood pressure. The six hour test involves the collection of urine and sampling of blood. Some of the needed 20 volunteers will be asked to return for a followup study, Moran said.

Benefits to volunteers, Moran said, include an inside look—and personal experience—in how scientific research is conducted, individual health insight, and $50 in compensation.

For further information and/or to schedule an appointment, call the division of nephrology from 9 a.m. to 5 p.m, Monday through Friday at (415) 497-5984.

CLINIC HOLDS OPEN HOUSE

STANFORD—

Come see the newly renovated Stanford University Clinic! After months of dust, debris and "do not enter" signs, the first phase of the $6.5 million facelift is ready for your perusal at an open house March 16 from 4-6 p.m.

"Everyone from the medical center and the community is invited to come see our new facilities," said Vera Waechter, clinic assistant director.

The clinics included in the completed portion of the renovation are.surgery, urology, cardiovascular surgery, internal medicine, nephrology, immunology, hemotology, allergy, gastroenterology, and endocrinology.

Patients will be seen in the clinics' old facilities on March 16, and in the new facilities on March 19. Staff will complete the move to the new facilities over the weekend so as not to interrupt patient visits, Waechter said.

The clinic renovation will provide newly designed patient rooms; examination rooms offering privacy and enough room for family members and staff; convenience-designed patietn registration and waiting areas; conveniently located service for handicapped patients; outpatient pharmacy and specimen collection area located near the main entrance; more conveniently located conference rooms; and a better overall atmosphere.

The renovation of the clinic is scheduled for completion in late 1985.

RESEARCHERS STUDYING RELATIONSHIP BETWEEN EXERCISE AND COMMON DRUG

STANFORD—

Researchers at Stanford are studying whether exercise and beta blockers together more effectively control high blood pressure than using those drugs without a fitness program.

The study could be significant, because earlier studies conducted elsewhere have suggested that beta blockers—administered to millions of hypertensive patients worldwide—limit the cardiovascular system's ability to benefit from exercise, said Michael Savin, Ph.D., a research associate in the Medical Center's division of cardiology.

"This is a dilemma," said Savin, "because many patients on these drugs could potentially derive a great deal of benefit from exercise. So we are encouraged that preliminary results of another recent study conducted here are indicating that healthy men can benefit from exercise while taking beta blockers."

Savin said he expects to present preliminary results of that study of 39 healthy volunteers to the National Scientific Meeting of the American College of Cardiology in Dallas later this month.

The next step, said Savin, is to learn if men given beta blockers to treat high blood pressure will also benefit from regular exercise. The study will also be taking a close look at the ability of exercise to lower blood pressure with or without medication.

The current study is being conducted in conjunction with physicians at Duke University, Durham, N.C.

The Stanford group is looking for 45 male volunteers between about 25 and 55 years of age who have untreated high blood pressure but are otherwise healthy. Participants should not have participated in regular endurance exercise during the past six months.

Before beginning an intensive eight-week exercise program, volunteers will be divided into three groups. One group will receive the drug atenolol, another group will receive propranolol, and a third group will take a placebo (an inert powder which resembles a drug but has no pharmacologic effect).

Atenolol and propranolol are two of the most common forms of beta blockers, which are the most widely prescribed category of cardiovascular drugs, accounting for about $400 million sales annually in the United States, said Savin. By attaching themselves to receptors at nerve endings in the body, these drugs act as barriers to halt incoming chemical messengers which otherwise would tell the heart to speed up.

Simultaneously, these drugs also lower blood pressure, but the precise reasons why are not fully understood, Savin said.

The current study offers volunteers a thorough physical exam, the potential for a regimen which will control blood pressure, and the likelihood that each volunteer will leave the program in better shape, said Dr. H. Robert Superko, medical director of the project.

Potential applicants are invited to call Savin or Craig Hoover, cardiology research assistant, at 497-9646 between 2 and 4:30 p.m. Monday through Friday for more information.

Other Stanford researchers involved in the project include Dr. William Haskell, clinical associate professor of cardiology; and Dr. Donald C. Harrison, chief of the cardiology division.

(Members of the news media are may contact Savin directly at (415) 497-6254).

VOLUNTEERS NEEDED FOR STUDY OF ANOREXIA, AN UNUSUAL DIETARY DISORDER

STANFORD—

Stanford University Medical Center researchers are looking for 40 volunteers to participate in a study of anorexia nervosa, a disorder in which young women diet obsessively, sometimes to the point of starvation.

The researchers plan to study the relationship between anorexia nervosa and body levels of zinc, an essential mineral.

"There are many similarities between the clinical picture of zinc deficiency and anorexia nervosa," explained Dr. Rebecca Katz, who is conducting the study. "Both conditions are characterized by weight loss, growth retardation, loss of appetite, decreased taste acuity, lack of menstrual periods in females, delayed sexual development, mood changes, and hair and skin abnormalities."

Volunteers must be anorexic individuals under 21, said Katz. Those accepted into the study will undergo a medical history and physical examination, which includes taking blood and urine samples. Volunteers will also be asked to keep a record of everything they eat for three days, Katz added.

The study is being conducted at Children's Hospital at Stanford through Stanford medical school's division of adolescent medicine. Individuals who would like to volunteer may call Dr. Katz at (415) 327-4800, extension 538, weekdays between 8 am and 5 pm.

STANFORD PHYSICIAN EXPOSES HYPOGLYCEMIC MYTH

STANFORD—

Science and medical writers: Copies of **Stanford Medicine** on which this article is based are available on request if not included with story.

Hypoglycemia, not enough sugar in the blood, is often a misdiagnosed disease prompting patients to undergo major, expensive and unnecessary changes in their lifestyles, says a Stanford University endocrinologist.

Writing in the winter issue of **Stanford Medicine**, Dr. Carlos Camargo, clinical associate professor of medicine, attributes the wrong diagnosis to an "unwarranted reliance by physicians and patients on the results of a glucose tolerance test."

Camargo calls it "one of the most misused and misinterpreted tests in medicine."

Despite a new warning by the American Diabetes Association on the false diagnosis of hypoglycemia, Camargo points out, "physicians and patients still grab onto it just to have a medical diagnosis for what are often ill-defined symptoms."

"At the Stanford Endocrine Clinic we continue to see many patients diagnosed as having hypoglycemia," Camargo says. "Frustrated with their altered lifestyle, they seek a second opinion or different therapy."

Camargo describes a hypothetical typical patient, Mr. Jones, who consulted his physician because of a lack of energy, weakness, palpitations, fatigue, dizziness, headaches, emotional instability, and irritability. Jones first suspected hypoglycemia. A relative had informed him of the possibility.

Mr. Jones' doctor did a routine physical which showed no signs of the disease. Then to be sure, the doctor ordered a glucose tolerance test. After fasting overnight Mr. Jones reported to the laboratory, where the technician asked him to drink a syrupy concoction containing 75 to 100 grams of sugar.

"In reality, no one would ever ingest this much pure sugar at any one time," writes Camargo. But the technician sent the results to Mr. Jones' physician who, like others, made his first mistake in diagnosing hypoglycemia.

-more-

March 6, 1984

All too often, according to Camargo, physicians and patients are unaware that perfectly normal people may have blood sugar levels as low as 30 milligrams (mgs) during the five-hour test. The normal fasting levels range from 70 to 110 mgs at some point during the test. And according to a recent study, 10 percent of 650 patients without evidence of diabetes or carbohydrate intolerance had blood sugar levels less than 50 mgs at some point during the test. None had hypoglycemic symptoms.

Fasting affects blood sugar levels, a fact that's often misunderstood, Camargo says. The original "normal" levels were established by testing adult males. Not until many years later did doctors realize that age and gender significantly influence those levels. And there are differences in blood sugar levels between men and women.

"True hypoglycemia is a serious medical problem," Camargo writes. "It's not a disease, but rather an indication of an underlying disorder. It may be caused by a excess insulin, pituitary and adrenal failure, hepatic disease, malignant tumors, or even ingestion of drugs or alcohol. It can also be reactive, surfacing after meals in patients who have had surgery on their stomach or upper bowel."

Dramatically effective therapy is often available for hypoglycemia, Camargo says. But patients like Mr. Jones who are wrongly diagnosed are often unnecessarily placed on unusual diets, such as those emphasizing high protein foods. Mr. Jones gained 45 pounds before seeking a second opinion.

"Support" groups, such as hypoglycemic foundations and magavitamin hypoglycemic centers, add to the problem, Camargo believes.

"They offer patients bizarre therapies such as 'spleen detoxification' with carrot juice, or injections. These organizations' publications also expound the hypoglycemic myth."

SHUMWAY, HARRISON POINT TO RESEARCH DIRECTIONS IN NEW BUILDING

STANFORD—

Stanford scientists will soon begin using laboratories in the newly completed Dr. Ralph and Marian Falk Cardiovascular Research Center to learn more about how sick hearts may be rejuvenated, mended, replaced, or even prevented.

Dedication ceremonies were slated Tuesday, March 6, for the 52,000-square-foot, $14 million building, which houses the academic and research activities of the department of cardiovascular surgery, under Dr. Norman E. Shumway, and the division of cardiology, headed by Dr. Donald E. Harrison.

In interviews prior to dedication ceremonies, both Harrison and Shumway discussed the research their teams are planning in coming years.

For Harrison, approaches range from the very large—preventive studies involving patients and society—to microscopic relationships between cells where heart attacks begin. In cardiovascular surgery, Shumway sees improvement in heart/lung transplantation and development of a mechanical assist device for the patient's own heart.

The left ventricular assist device (LVAD), already being tested in calves under the direction of Dr. Philip E. Oyer, can aid the left ventricle or pumping chamber of the heart, where most heart disease tends to be found. Unlike a total artifical heart, Shumway says the LVAD is reversible since the device can be removed after the heart heals.

But the LVAD could one day serve as a permanently implanted assist, Shumway believes, powered by a rechargeable battery.

"This is what Oyer (an associate professor of cardiovascular surgery) and our colleagues have on the drawing board—a power source for the LVAD that could be transmitted through the skin from an electrical transformer belt worn around the waist. The belt would drive its power either from rechargeable batteries or conventional 110-volt sources," Shumway said.

The present LVAD model includes electric wires, which while intrusive, are preferable for patients to the air hoses found in totally impltantable hearts.

"I don't think there's a real future for any artificial device that requires some kind of tethering or wires or air hoses protruding through the patient's skin unless its used only on a temporary basis," Shumway said.

The first LVAD implants are tentatively scheduled for this year, Oyer has said.

While research for mechanical assist devices continue, Shumway says he and his team will be continuing to find ways to preserve lung tissue outside the body to enable more heart/lung operations to be performed. Since March 1981, 17 such combined transplant have been performed. The procedure is limited, partly because many potential donors become unusable because lung tissue has been damaged, he said.

2-2-2 Harrison and his cardiology colleagues are turning to specially designed computer programs which will measure changes in blood vessels caused by atherosclerosis, the major cause of heart attacks and strokes. As part of the research, patients with various degrees of narrowing of their blood vessels will be examined.

Later, the patients will be reexamined after they have changed their diets or lifestyle, exercised or taken appropriate drugs. Physicians will see if these potentially risk reducing changes have altered the extent of atherosclerosis and the incidence of heart disease, Harrison explained.

Abnormal heart rhythms, called arrhythmias, are being studied at their genesis in cardiac cells grown in tissue culture. This research, says Harrision, should help scientists develop improved medications, or perhaps even surgical interventions, to help patients whose hearts beat irregularly.

Harrison says cardiology researchers swill also be looking to the nervous system as a partner in heart function. Messages moving from or to the brain can influence heart function, particularly for persons whose bodies must compensate for damaged heart muscle. Various drugs offer the promise of influencing the signals which can help the heart compensate for damaged muscle.

The dedication ceremony included afternoon public lectures by Dr. Peter L. Frommer, deputy director of the National Heart Lung and Blood Institute, who was to discuss the partnership between government and academic institutions in pursuit of science. One of the nation's most eminent cardiologists, Dr. Eugene Braunwald of Harvard Medical School, was to talk about three decades of progress in cardiology, including drug interventions and research leading to risk reduction.

A third speaker, Dr. C. Walton Lillehei, emeritus professor of surgery and cardiovascular surgery at the University of Minnesota, described the past 30 years in his field, including development of heart transplantation under Shumway's direction at Stanford.

The lectures were to be followed by a formal dedication at the new research center. William R. Kimball, president of the Stanford University Board of Trustees is to preside.

Harrison, past president of the American Heart Association, said the new center should facilitate heart research by making possible closer interaction between surgeons and cardiologists.

"This facility is bringing together in close proximity both the medical and surgical cardiologic groups," Harrison said. "That will allow us to have integration of our programs in a much more organized way."

The research building is adjacent to the hospital and clinics, where patient care will continue. Laboratory space fills the two lower floors, while the top floor houses faculty and staff offices, conference rooms and other facilities in support of the academic program.

The building is named for Ralph and Marian Falk of Chicago. Mrs. Falk, the largest individual donor on the project, had selected Stanford as the site to memorialize her husband, a surgeon and co-founder of Baxter Laboratories, developers of prepackaged intravenous units.

The amount of Mrs. Falk's donation has been withheld at her request.

Other major donors include a $4 million grant in 1979 from the Max C. Fleischmann Foundation of Nevada. A final institutional grant of $400,000 came from the Conrad Hilton Foundation. Individual donors totaled more than 100 persons.

Hellmuth, Obata and Kassabaum, Inc. of San Francisco designed the building, and Dillingham Corp. of San Jose was the general contractor. The project was begun in February 1982.

ADVANCE FOR RELEASE A.M. WEDNESDAY MARCH 7

SCIENTISTS FIND KEY IMMUNE SYSTEM GENE

STANFORD—

In research with profound implications for immunology, a team of scientists—led by a medical microbiologist from Stanford University—has isolated the elusive gene believed to regulate the body's response to tissue transplants and to infectious agents.

The effort was led by Dr. Mark Davis, assistant professor of medical microbiology at Stanford University School of Medicine.

His collaborators in the work, published simultaneously in two articles in the March 8 issue of Nature, are Dr. Stephen Hedrick of the UR ersity of California in San Diego, Ellen Nielsen of the National Institute of Allergy and Infectious Disease, and Dr. David Cohen and Joshua Kavaler in Davis' laboratory at Stanford.

The newly isolated gene had been sought unsuccessfully for at least a decade by researchers around the world, according to Davis.

The gene—a very small portion of the hereditary material, DNA—contains a blueprint for a substance produced by "T-cells," one of two major cell types responsible for the body's immune responses. The gene, which has been cloned by the researchers, codes for a substance called the T-cell receptor.

Davis' research team found the T-cell receptor gene from mice; it is known to be nearly identical to the human gene, he said. Another research group from Canada reported in the same issue of Nature32 finding a gene from humans with similar properties, he added.

To work properly, the immune system depends on two major types of cells, called B-cells and T-cells, Davis explained.

B-cells produce antibodies, molecules that participate in the body's fight against bacterial and viral disease.

T-cells play a wider variety of roles in the immune system, Davis said, including regulation of the actions of B-cells. They also control the body's response to tissue transplants, and can directly kill viruses and certain types of tumor cells, he explained.

Both B-cells and T-cells must recognize foreign substances in the body in order to carry out their jobs. They do so by means of specialized receptor molecules located in their membranes or on their surfaces.

In recent years, a lot has been learned about how B-cells perform this task by means of their antibody receptors, Davis said.

But so little has been understood about how T-cells detect invading agents that the search for the elusive T-cell receptor and its encoding gene had become a challenge to many researchers in the field, he said.

With the T-cell receptor gene finally "in hand," scientists can now begin to answer many questions about the immune system that have baffled immunologists, Davis said.

Foremost, it is now possible to learn how T-cells work—how they recognize both foreign substances and self. This should lead to a better understanding of the immune system in general and of transplant rejection and viral infection, Davis predicted.

Also, it should now be possible to figure out how many types of T-cells there are and how they differentiate, what the roles of the different T-cell types might be, how they regulate the immune response, and how they combine with B-cells to destroy disease-causing agents, Davis said.

Discovery of the T-cell receptor gene may provide more immediate clinical benefits in addition to clarifying basic unanswered questions about immune system function, said Davis. These would include the ability to identify different classes of T-cell tumors, and the potential for developing specific T-cell tumor identification markers that could aid in cancer therapy.

Davis and his colleagues used a novel, indirect method to find the T-cell receptor gene. They capitalized on their knowledge about the genes that code for B-cell antibodies in developing the approach. They also made use of the fact that B-cells do not produce any T-cell receptor.

B-cells produce antibodies, molecules that sit on the surfaces of B-cells and also rove through the body's tissues on the lookout to bind and mark for destruction invading material. Different varieties of B-cells are highly specialized to make specific antibody molecules that can latch onto a particular foreign substance, called an antigen.

Although all B-cells start out with identical antibody-coding genes, segments of these genes can be "mixed and matched" as B-cells mature. This rearrangement of DNA enables each type of B-cell to develop a "tailormade" response to a particular foreign antigen, Davis explained.

Davis and his colleagues reasoned that T-cells would also have to undergo rearrangement of their DNA in order to produce enough receptor variety to be able to specifically recognize the many different substances that can enter the body.

They also reasoned that T-cells and B-cells were actively expressing different portions of their DNA.

The researchers then searched for those parts of the DNA that were active in T-cells but inactive in B-cells. In this DNA, they found a gene that seemed to be completely rearranged in the different lines of T-cells they examined.

Davis and his colleagues determined the sequence of nucleotides in this purported T-cell receptor gene and found that it coded for a molecule with characteristics very similar to antibody.

Thus, T-cells seem to do their job of specifically recognizing foreign substances in the body with a molecule very similar to the B-cell antibody.

The scientists began the project as researchers at the National Institute of Allergy and Infectious Diseases (NIAID), a division of the National Institutes of Health in Bethesda, Maryland.

The research was funded by grants from the National Institutes of Health and fellowship support from the Leukemia Society of America.

VOLUNTEERS NEEDED FOR DIABETES RESEARCH

STANFORD—

Stanford University researchers are looking for volunteers to participate in a study into the effects of aging on the ability of the pancreas to secrete insulin.

Volunteers with noninsulin treated diabetes are needed for this as well as other ongoing research at the clinical research center of Stanford Medical Center.

People without diabetes are also needed to participate in control groups.

Participants will be offered various medical and health evaluations free of charge, including blood sugar, insulin, liver and kidney function tests, cholesterol, hemoglobin, and cardiogram. They must be between 20 and 80 years old, male or female; and be in good general health.

For further information call Dr. Chris Donner or Dr. Elizabeth Fraze, at (415) 497-6973; or Ann Coulston, R.D., at (415) 497-5430.

SCIENTISTS HELP OPEN HEART RESEARCH FACILITY

STANFORD—

(Science reporters, city desks news directors: a news conference marking the opening of the building is scheduled at 10 a.m. in the foyer of the building. Dr. Donald Harrison, head of the cardiology division; and possibly Dr. Norman Shumway, chairman of the department of cardiovascular surgery, will be available for comment and questions. It is not known now whether the guest speakers will be at the news conference. Parking is available in the parking lot adjacent to the building. Tours of the building may be arranged immediately after the conference.)

(This release transmitted to certain West Coast Points via Business Wire 3/1.)

A 52,000 square-foot facility intended to bring together two of Stanford University Medical Center's most widely known programs will be dedicated Tuesday March 6.

The Dr. Ralph and Marian Falk Cardiovascular Research Center houses the academic programs and laboratories of the department of cardiovascular surgery under Dr. Norman Shumway, and the division of cardiology headed by Dr. Donald Harrision.

At a public lecture, Dr. Peter L. Frommer, deputy director of the National Heart Lung and Blood Institute, will discuss the partnership between government and academic institutions in pursuit of science. One of the nation's most eminent cardiologists, Dr. Eugene Braunwald of Harvard Medical School, will discuss three decades of progress in cardiology, including drug interventions and research leading to risk reduction.

A third speaker, Dr. C. Walton Lillehei, emeritus professor of surgery and cardiovascular surgery at the University of Minnesota, will talk about the past 30 years in his field, including development of heart transplantation under Shumway's direction at Stanford.

March 1, 1984 -more-

The lectures begin at 2 p.m. at Sherman Fairchild Auditorium at the Medical Center.

A formal dedication at the new research center is slated for 4:30. William R. Kimball, president of the Stanford University Board of Trustees is to preside.

Harrison, past president of the American Heart Association, said the new center should facilitate heart research by making possible closer interaction between surgeons and cardiologists.

"This facility is bringing together in close proximity both the medical and surgical cardiologic groups," Harrison said. "That will allow us to have integration of our programs in a much more organized way."

The $14 million facility is adjacent to the hospital and clinics, where patient care will continue. The two lower floors of the new building provide lab space, while the top floor houses faculty and staff offices, conference rooms and other facilities in support of the academic program.

Mrs. Falk, the largest individual donor on the project, had selected Stanford as the site to memorialize her husband. a Chicago surgeon and co-founder of Baxter Laboratories, developers of prepackaged intravenous units. She had said she admired the work of Shumway.

The amount of Mrs. Falk's donation has been withheld at her request.

Other major donors include a $4 million grant in 1979 from the Max C. Fleischmann Foundation of Nevada, which allowed for planning. A final institutional grant of $400,000 came from the Conrad Hilton Foundation. In addition, there were more than 100 indvidual donors to the building.

The building was designed by Hellmuth, Obata and Kassabaum, Inc. of San Francisco. Dillingham Corp. of San Jose was the general contractor. Site clearance for the project began in February 1982.

ADVANCE FOR RELEASE AFTER 10 A.M. EASTERN TIME MONDAY, MAY 7, 1984

FIRST NATIONAL STUDY OF DRUGS FOR HEAD AND NECK CANCER TREATMENT GIVES MIXED RESULTS

STANFORD—

Anti-cancer drugs do not significantly improve survival rates for patients with head and neck tumors, compared to standard surgery and radiation treatments, a national study concludes.

But the drugs tested promoted tumor shrinkage in one out of three patients who received them, according to results of the study, which was the first major national trial of chemotherapy in head and neck cancer patients.

Therefore, new and more powerful drug regimens with greater effectiveness should be tested as a supplement to standard head and neck cancer therapy, said Dr. Charlotte Jacobs, assistant professor of medicine at Stanford University School of Medicine, one of the researchers on the study.

Jacobs reported the findings Monday morning May 7 at the annual meeting of the American Society for Clinical Oncology in Toronto, Canada.

The study, by the Head and Neck Contracts Program, followed 443 patients between 1978 and 1982. The investigation was a collaborative effort funded by the National Cancer Institute involving 13 medical institutions nationwide. Jacobs spoke on behalf of the joint effort.

Although head and neck tumors are relatively rare, accounting for approximately 6 percent of all malignancies, they are among the most debilitating cancers, Jacobs said.

The patients in the study all had advanced cancers located in the tongue, floor of the mouth, tonsils, or vocal cord regions, Jacobs said.

With standard head and neck cancer therapy, consisting of surgical removal of the tumor and postoperative radiation treatments to obliterate lingering disease, about 50 percent of patients with advanced cancers would be expected to survive five years, she explained.

The patients were randomly assigned to three groups. All received the standard treatment program of surgery and radiation therapy.

One group of patients also received a dose of anti-cancer drugs—cisplatin and bleomycin—prior to surgery. A second group of patients received the chemotherapy dose prior to surgery, followed up by six months of treatment with cisplatin following postoperative radiation therapy. The control group of patients underwent only the surgery/radiation combination.

Two-year survival rates in all three groups were approximately 60 percent, Jacobs reported, which is consistent with the survival expected for surgery/radiation alone.

Even though the study showed no increase in survival when the drugs were added to established therapy programs, there were some positive results, Jacobs said. Preoperative chemotherapy shrank tumors to smaller than one-half the original size in one third of the patients tested.

Furthermore, the study revealed that patients tolerated the drugs well, with few adverse side effects. "These positive findings suggest that current, more efficacious drug regimens should be tested for their potential in improving survival for head and neck cancer patients," Jacobs said.

The study was also significant, Jacobs added, because it was one of the first multi-institutional efforts to focus on treatment of head and neck tumors. Because it is a rare form of cancer, only by pooling results from patients all over the country can researchers study the problem, she noted.

Institutions involved in the study, in addition to Stanford University, were Boston University and Boston Veterans Administration Hospital, Memorial Sloan-Kettering, Thomas Jefferson University, University of California (Davis), University of California (San Francisco), University of Cincinnati, University of Maryland, University of Michigan, University of Pennsylvania, University of Pittsburgh, University of South Florida, and University of Texas.

ADVISORY—CONFERENCE MAY 9-11 FOCUSES ON EMERGENCY TRANSPORT

STANFORD—

Aviation lingo may be almost as common as medical terminology will be held May 9-11 by Stanford University Hospital's Department of Critical Care Transport.

Instructors and participants from around the nation and several foreign countries are scheduled to discuss the most effective ways of getting critically ill or injured patients to the hospital, announced Kaaren Peterschmidt, a nursing education coordinator and an organizer of the conference.

Topics range from "Carrier Selection: The Latest in Jets and Rotorcrafts," scheduled at 10:35 a.m. Friday, to a panel debate at 11 a.m. that day on whether physicians should be included in the transport team.

Two European authorities on critical care transport, Dr. Miguel Martinez-Almoyna of the Urgent medical Aid Service of Paris, and Peter Dangel, head of anesthesia and intensive care at Zurich, Switzerland's children's hospital, will talk about the role of critical care transport in their countries. One of Dangel's lectures is entitled "Mountain Rescue in Switzerland: Physiologic and Technical Problems."

Equipment displays are scheduled on Friday afternoon, and on Saturday morning, a variety of fixed-wing and helicopter aircraft used in transport will be on display at San Jose Airport.

Other specialized topics include lectures on the transportation of infants and expectant mothers, how to administer medication while in motion, and financial and governmental issues related to transport.

The conference, open to pre-registered health professionals, will be held at Hyatt Rickeys Hotel in Palo Alto.

MARKEY TRUST FUNDS PREDOCTORAL STUDENTS AT STANFORD MEDICAL SCHOOL

STANFORD—

The Lucille P. Markey Charitable Trust of Miami has given a $360,000 five-year grant to Stanford University School of Medicine for fellowship support of predoctoral students in basic medical sciences.

Stanford is one of 15 institutions with strong biomedical research programs—including twelve medical schools and three universities—to receive a grant in the fellowship program, the Trust announced.

Each institution will receive $360,000 over a five-year period for partial support of three consecutive classes of students beginning in September 1984, said Louis J. Hector, chairman of the Markey Trust.

Support could be extended at each institution to a five-year term for each class, contingent on satisfactory review at the end of each class' second year, according to the Trust. This would extend the grant period and funding allotted each institution to seven years and $600,000.

"The generous grant from the Markey Trust will be used to support outstanding predoctoral students in our departments of biochemistry and structural biology," said Stanford Medical School dean Dominick P. Purpura. "This support is particularly welcome and appreciated since it comes at a time when student fellowship resources are dwindling."

In announcing the funding program, William P. Sutter, president and chairman of the Trust's fellowship committee said: "In recent years as the need for medical research fellowship funding has steadily increased, the amount of funding available has not kept pace, and this is particularly true for those just starting on their research career as predoctoral graduate students.

"It is our hope that these grants from the Trust will enable outstanding students to pursue their studies more effectively by virtue of lessened financial burdens," he added.

The Lucille P. Markey Charitable Trust was established in 1983, following the death in 1982 of Lucille P. Markey, owner of Calumet Farm, the world-famous Kentucky thoroughbred breeding and racing stable. Under the provisions of Mrs. Markey's will, the Trust's assets are used exclusively for support of basic medical research.

Other institutions receiving funds through the fellowship program are California Institute of Technology, University of California-Los Angeles, University of California-San Francisco, University of Chicago, Harvard University, Johns Hopkins University, University of Kentucky, Massachusetts Institute of Technology, University of Miami, Northwestern University, Rockefeller University, Washington University, University of Wisconsin, and Yale University.

STANFORD HOSPITAL'S NURSE WEEK (MAY 6-12)

HIGHLIGHTS ADVANCES IN NURSING PROFESSION

STANFORD—

Stanford Nurse Week, a celebration of nursing achievements in patient care, research, teaching and management, will take place May 6-12 at Stanford University Hospital (SUH).

A highlight of the week's activities will be a public lecture on the rising professional image of nursing by noted University of Michigan professors of nursing, Drs. Beatrice and Philip Kalisch. The festival also will feature tours and displays open to the public.

The weeklong event—an expansion of National Nurse Day on May 9—is a tribute to the growing influence of nursing in medicine, according to Gaye Bruce, R.N., chairperson of the Nurse Week organizing committee.

"Nurses are finally gaining the professional recognition they deserve," said Bruce. "Stanford Nurse Week provides an opportunity to let the community learn about the many ways in which nurses contribute to health care."

In honor of the event, Palo Alto Mayor Larry Klein has proclaimed May 6-12 Mid-Peninsula Nurse Week, Bruce added.

Major events open to the public include:

- Tues., May 8—Health Fair near the SUH main center cafeteria, from 9 a.m. to 4 p.m.. Exhibits, demonstrations and presentations explaining the role of nurses in patient care, education, and research.

Tours led by nurse docents will depart from the Health Fair area to visit hospital nursing units, intensive care facilities, operating rooms, emergency services, and the new medical rescue helicopter.

4-24-84

-more-

• Wed., May 9—Lecture on "Nursing Images: A New Challenge," featuring nationally known speakers Beatrice J. Kalisch and Philip A. Kalisch, from the University of Michigan. The lecture will take place in Fairchild Auditorium from 9 to 11 a.m., and will be repeated in the afternoon from 3:30 to 5:30 p.m.. A reception will be held in the Fairchild Auditorium lobby between presentations, from 2:30 to 3:30 p.m..

• Thurs., May 10—Health Fair and tours of SUH Hoover Pavilion nursing units, including special presentations on nursing's role in sports medicine, psychiatry, dermatology, and plastic surgery. Tours take place at 10 a.m., 2 p.m., and 3:45 p.m.. Shuttle vans to Hoover will depart from the Main Center entrance 15 minutes prior to tour departure times.

The weeklong tribute to nursing may be the first event of its kind, Bruce said, as nursing changes to encompass much more than bedside care.

"At Stanford Hospital, nurses are encouraged to get into other professional activities, such as education and research," she explained. "These opportunities for professional advancement have helped Stanford Hospital achieve notable success at nurse recruitment and retention," added Bruce, who is the SUH nursing department's coordinator for marketing and recruitment.

The program was conceived following a survey at Stanford Hospital which revealed that professional recognition is important to nurses who work in the institution, Bruce said. "This event pays tribute not only to the nurses at Stanford but to nurses everywhere," Bruce noted, adding "we are getting calls from nurses all over the country who have heard about the event."

Stanford Nurse Week "was the brainchild of Stanford nurses themselves who have been actively supported in the effort by SUH director of nursing Duane Walker, R.N.," Bruce said. More than 1,000 people are expected to participate in the event which has been in planning for over nine months, she added.

CHILDREN CAN LEARN ABOUT GOOD HEALTH AT FAIRE

STANFORD—

Children—and their families—will have the opportunity to learn about good health at the Children's Health Faire scheduled for Saturday, May 5, at Stanford Shopping Center.

Sponsored by Children's Hospital at Stanford and Stanford University Hospital, the event will feature more than 35 booths that will line the mall. All will offer hands-on experiences, exhibits and demonstrations aimed at teaching children about health related topics such as sports injuries, good nutrition, first aid and paramedic rescue, communicable diseases, and poison control.

Children will also be able to learn what to expect if they are admitted to the hospital, or require ambulatory surgery.

The Palo Alto Fire Department and Sheriff's Department, the Palo Alto Paramedics, Touchstone, and the Ronald McDonald House are just some of the community groups that will have booths at the faire.

The booths will be open to the public at no charge from 10 a.m. to 4 p.m. For more information call the Community Affairs Office at Children's Hospital at Stanford, 327-4800, ext. 363, or Stanford University Hospital's pediatrics department at 497-5351 or -5135.

STRUCTURES OF BIOLOGICAL MOLECULES REVEALED WITH NEW ELECTRON MICROSCOPE TECHNIQUES

STANFORD—

Scientists at Stanford University School of Medicine are using dramatic new techniques to study biological molecules in the electron microscope.

The new techniques, part of a multi-laboratory effort, are helping researchers explore the miniscule molecules responsible for processes basic to life, ranging from proteins that control communication between cells to the disease-fighting scouts of the immune system, known as antibodies.

Although looking at structures may seem easy, with objects as tiny as biological molecules, it is an enormous technological feat. The new techniques, being developed in the laboratories of two professors in Stanford's department of structural biology—Drs. Roger Kornberg and Nigel Unwin—overcome some major limitations of electron microscopy.

Because they are so tiny, the structures of most biological molecules can only be analyzed under the electron microscope if many copies of the molecule are aligned in orderly arrays, like trees in an orchard. Then, by combining information from all the assembled molecules, a picture of the "average" molecule can be calculated.

Kornberg and his colleagues have developed a way of making biological molecules line up, or crystallize, in a thin sheet.

Unwin's laboratory has found a way of freezing molecules, plunging them into liquid nitrogen at minus 160 degrees centigrade. Using the freeze technique with a low dose electron beam enables researchers to do away with stains that obscure detail in molecules being viewed. Eliminating stain also allows researchers to look at molecules in their natural aqueous solution, simulating conditions inside the living body.

(Both techniques build upon work by David DeRosier and Aaron Klug from the Medical Research Council Laboratory in England. The British team established a way of making three-dimensional pictures by tilting crystalline specimens in the electron microscope, then using sophisticated mathematics to transform the information into a picture of a single molecule.)

By opening this new window on the world of biological structures, the Stanford scientists expect to learn much more than molecular "anatomy"—they hope to use that knowledge to deduce how molecules perform many of the tasks basic to life.

"Our understanding hinges on having precise pictures of molecules so that we can think in specific terms rather than in cartoons," Kornberg explained.

Kornberg's approach to making molecular crystals could be compared to inviting people to a movie with limited seating and giving them comfortable swivel chairs to sit in. Initially, as people fill the swivel chairs they face in different directions. But when the movie begins, everyone turns to face the screen, thus creating a one-person-thick "crystalline" array.

In the molecular process, the swivel chairs are special fat molecules, called lipids, layered onto the surface of an electron microscope's examination grid. The molecules under study attach to the lipid "chairs" because the lipids have been modified to contain a binding site with special affinity for the molecule. As the molecules "sit down" on the lipids, at first they face in random directions. But in time the molecules swivel around to face the "movie screen" as chemical interactions occur, holding the molecules together in formation.

In a pilot study using antibody molecules, published last year in *Nature*, Kornberg and a colleague, Ed Uzgiris, established that this lipid binding technique produces two-dimensional crystals thin enough to be examined under the electron microscope. The electron microscope image of the disease-fighting antibody molecules revealed a flexible joint not previously known to exist.

The new approach has created excitement in the scientific community. Researchers have come to Stanford to learn and apply the technique, and the university is seeking a patent to cover commercial applications of the process.

Kornberg expects the crystallization approach to help provide new information on cellular complexes containing many proteins, such as those involved in the vital functions of DNA replication and protein synthesis.

"Just as you need to know the arrangement of components and parts to know how a machine works, you have to know how molecules are arranged in the complex systems and assemblies of the cell," Kornberg said.

Martha Fedor and Hans Ribi, investigators in his laboratory, already have made lipids linked to nucleotides and to DNA. These will be used to examine a host of molecules that interact with the hereditary material. An example under study in Kornberg's laboratory is RNA polymerase, an enzyme that helps determine what proteins each cell makes.

The other new technique, developed in Unwin's laboratory, has been used to study tiny tunnels between cells, called "gap junctions." Some of the work carried out by Unwin is described in articles in the February issue of *Scientific American* and in the February 18 issue of *Nature*.

These tunnels—made of a protein called connexon—open and close, controlling communication between neighboring cells. Although the tunnels play a crucial role in coordinating tissue growth and metabolism throughout the body, until recently how they opened and closed was one of biology's mysteries.

Unwin and his colleagues have learned that the connexons twist open and shut because of subtle structural alterations caused by changes in calcium levels inside cells.

"Understanding how connexons work is important because they facilitate communication between cells, enabling them to work in a coordinated way, to grow and function together," explained Unwin. "If these channels are defective or closed, then cells can't communicate well. The result could be haphazard growth, perhaps even malignancy. We are studying the connexon protein to find out how it regulates cell-to-cell communication."

The connexon is a protein made of six identical subunits—like columns standing on end—arranged in a circle, enclosing the tunnel. It operates much like a diaphragm controls the opening in the lens of a camera, Unwin noted. As the columns tilt slightly against each other, the tunnel opens; as they straighten up, the tunnel disappears.

"This gating effect is crucial to the life of tissues," Unwin said. "Among other things, it seals off cells that die, preventing the loss of vital nutrients from adjacent healthy cells."

Unwin stressed the importance of other studies in his laboratory such as the work of two postdoctoral researchers, Ed Gogol and Santosh Sikerwar, who are looking at aduitional structural properties of gap junctions between cells.

Visiting researcher Alain Brisson and a graduate student named Peter Ennis are looking at molecules involved in nervous system function. In particular they are studying a protein in cell membranes that specifically binds to acetylcholine, a chemical messenger released by nerve cells.

Graduate student Ron Milligan is studying ribosomes, the cellular structures where most protein synthesis takes place, Unwin said.

The structural approach to biological systems has been given insufficient attention in recent years, Kornberg believes, because the technology has been difficult and laborious to work with.

Kornberg summed up the "technology barrier" the new techniques help overcome.

Although x-ray diffraction and electron microscopy are useful for determining the structures of molecules that form crystalline substances, not many biological substances readily crystallize, he said.

Even when a biological substance can be obtained in crystalline form—as with the connexon protein—x-ray diffraction is so difficult and tedious that it can take years to solve the molecule's structure, Kornberg added.

Electron microscopy is speedier but it can reveal detail only in a very thin "slice" of crystal; large three-dimensional crystals are too thick for the electron beam to cleanly penetrate.

The powerful electron beam can destroy thin specimens unless they are encased in a special stain. With the protective coat of stain, however, only contours are visible while the insides of the specimen are obscured from view.

The techniques under development by the Stanford researchers in the department of structural biology—crystallizing biological molecules in a thin, two-dimensional sheet, and viewing the molecules in the "nude" without stain—have begun to crumble these technology barriers.

PALO ALTO PLANNING COMMISSION REVIEWS MODERNIZATION PLAN

STANFORD—

Two Palo Alto City Planning Commission members said Wednesday that Stanford University should provide an alternative housing site if a parking lot on housing-designated land is permitted next to the hospital's modernization project.

City planning staff members had recommended that zoning and city comprehensive plan changes be permitted to allow parking at the 3.06-acre heliport site, tentatively earmarked by the commission for housing.

"But I am loathe to give up the housing designation on that site without another," commission chairman Helene Wheeler told a preliminary hearing reviewing the environmental impact report for Stanford's $110 million hospital modernization project.

Concurring with Wheeler, Commissioner Mark Chandler added, "I am concerned that if another site is designated for housing, it is done so in a way that there are assurances that the housing will actually be built there."

Wheeler said potential sites for housing include vacant land near the proposed project on Welch Road. She said the commission should make no decisions on the matter at Wednesday's session and invited Stanford to recommend potential housing sites on university-owned land in the Palo Alto city limits.

The university has proposed building at 1100 Welch Road a 42-unit facility for patients and family undergoing longterm care at the hospital, as well as 108 apartment units primarily for medical center related employees. Plans for the 1,100 unit Stanford West housing project on a 46-acre site across Willow Road from the medical center were shelved last summer when the university and the city could not agree on conditions of approval set by the Palo Alto City Council.

The Planning Commission has scheduled a May 2 public hearing at which it can recommend action to the City Council on Stanford's request.

Lawrence G. Crowley, vice president for medical affairs and president of the hospital board, told the planning commission the project, under development for more than three years, is needed "to allow us to be much more efficient and to provide the most modern" patient care facility possible.

Stanford has proposed that 218 parking spaces be located adjacent to the heliport, between Welch Road and Blake Wilbur Drive. In 1987, when the heliport is expected to be relocated to the roof of the modernized hospital, Stanford has proposed converting the helipad to an additional 191 parking spaces.

The site is currently designated in the city's comprehensive plan as Multiple Family Residential, although the city has postponed rezoning the property from Office Research (which permits the heliport and parking) at Stanford's request pending completion of a medical center parking plan. That plan was recently finished and presented to city officials.

-more-

4/19/84

Ken Schreiber, city planning director, recommended that zoning be changed at the heliport site to Major Institution/Special Facilities. While he noted that the loss of potential housing "is a serious concern," he added that the new designation would give the hospital maximum flexibility to provide an economical parking solution while giving the city maximum control over the site, since the recommended zoning designation would severely limit alternative uses there.

In his opening remarks to the commission, Schreiber said "Stanford University Hospital is not a typical non-residential development. They are not proposing office and other commercial development that can be located in another part of the Santa Clara Valley" or elsewhere.

"The hospital has provided a very highly valued community service and the high quality health services of the hospital is a very important community objective."

He added, in response to some community concerns about the potential for greatly increased traffic and need for parking, that he believes that economic pressures and the limit on the increase in beds at the hospital will keep employment growth—hence increased traffic in the area—at a modest level.

Wednesday's hearing was authorized to review environmental and land use concerns. Architectural and health care needs are considered by other reviewing bodies. Plans for the buildings themselves will be scrutinized by the city's architectural review board May 3.

Other requests have already been granted, including approval by the state to issue up to $85 million in tax exempt bonds to finance portions of the project.

When completed in several years, the modernization will provide new, more modern nursing units and other facilities, including a new surgical suite. A four-story building with 190 new patient rooms will replace current outmoded facilities.

STANFORD HOSPITAL EXPERIENCES BABY BOOM

STANFORD—

Stanford University Hospital is having a baby-boom.

According to Marilyn Swarts, assistant clinical nursing coordinator for labor and delivery rooms, 312 babies—the largest monthly tally in more than 20 years—were born during March at Stanford. Births last exceeded 300 in August, 1961, with 314.

Swarts said deliveries then declined, probably in part because El Camino Hospital opened that year. After hitting a low of 141 in January, 1972, births averaged around 220 a month until last year.

"We definitely have seen a steady increase," Swarts said, adding that she hoped Stanford's reputation catalyzed the trend.

"We like to feel part of it," she said. Swarts added that she thought the upswing also reflected an increasing birthrate in the community.

Private physicians on the hospital's gynecology and obstetrics service are all seeing an increase, she said.

"What we're seeing more of is the older person who has had a career and is having a baby."

Two other local hospitals reported no increases last month. El Camino Hospital listed 221 births and Sequoia Hospital had 70, about average for those hospitals, spokeswomen said. The Birth Place, a local birth center, reported that an unusually large number—five of an expected six—of its March deliveries were transferred to Stanford for medical reasons, such as an anticipated cesarean section or breech birth.

Both The Birth Place and El Camino reported a gradual increase in births over the last couple of years. If the trend continues at Stanford, its old record—360 babies born in May, 1961—might be broken.

FOR IMMEDIATE RELEASE

(Editors, News Directors: The following is a shortened version of a release mailed March 7, 1984. It is being rereleased because of the continued need for volunteers).

VOLUNTEERS NEEDED FOR HIGH BLOOD PRESSURE STUDY

STANFORD—

Stanford researchers were continuing to seek volunteers for a study of whether an exercise program and medication are more effective against high blood pressure than drugs alone. The study also is g a close look at the ability of exercise to lower blood pressure without medication, said Dr. H. Robert Superko, medical director of the project.

Volunteers should be men between about 25 and 55 years of age who have untreated high blood pressure but are otherwise healthy. They should not have participated in regular endurance exercise during the past six months.

The study offers volunteers a thorough physical exam, the potential for a regimen which will control blood pressure, and the likelihood that each volunteer will leave the program in better shape.

The medications being tested are beta blockers, among the most commonly prescribed drugs in this country.

Potential participants are invited to call Craig Hoover, cardiology research assistant, at 497-9646 between 2 and 4:30 p.m., Monday through Friday, for more information.

STUDY LOOKS AT PSYCHOSOCIAL CONCERNS OF RECOVERED CANCER PATIENTS

STANFORD—

A majority of patients treated for the cancer known as Hodgkin's disease resume normal daily lives despite the emotional stress of experiencing malignant illness, Stanford University Medical School researchers have found.

But the researchers also found that the social and psychological challenges facing recovered cancer patients can mar successful re-entry to society for some.

In the first longterm follow-up study to investigate quality of life among patients treated for Hodgkin's disease, researchers found that most former patients were able to obtain full or part time work, and many who wanted to do so were successful in having children.

The researchers also learned that depression was a serious aftermath of cancer in about one of five patients, and difficulties on the job and lack of energy were experienced by approximately two out of five former Hodgkin's patients.

"The study indicates that 60 percent of treated Hodgkin's disease patients are doing very well, while approximately 40 percent are experiencing some psychosocial problems," said Patricia Fobair, clinical social worker who coordinated the study at Stanford University Medical Center.

"Although we do not know whether or not these figures would differ in a cross-section of the population at large, the results suggest that vocational rehabilitation and psychological counseling could be important components in an overall treatment program for Hodgkin's disease," Fobair added.

The cross-sectional study was based on interviews with 401 Hodgkin's disease patients treated at Stanford during the last 21 years. Fobair stressed the preliminary nature of the data and lack of a control group of non-cancer patients for comparison purposes.

Fobair was scheduled to present the preliminary, as yet unpublished, findings Thursday April 12 at an American Cancer Society meeting in San Mateo, CA.

Dr. Richard Hoppe, assistant professor of radiology at Stanford University School of Medicine, headed the investigation. Other members of the research team include Dr. Joan Bloom from the School of Public Health at the University of California in Berkeley, and Dr. David Spiegel, assistant professor in Stanford Medical School's department of psychiatry and behavioral sciences.

The study was funded by a grant from the Robert Wood Johnson Foundation of Princeton, New Jersey.

-more-

4/13/84

Hodgkin's disease, a cancer of the lymphatic system, strikes young adults, most frequently individuals in their teens, 20s or early 30s. With about 9,000 new cases reported each year in the United States, Hodgkin's disease has one of the highest cure rates of any malignancy. Due to improvements in treatment, which generally includes radiation therapy, drug therapy, or a combination of the two, nearly 80 percent of patients who receive proper therapy can expect near-normal lifespans.

Because such a large fraction of patients fully recover from the disease and face a full lifetime ahead, how to help foster the social and psychological rehabilitation of Hodgkin's disease patients is a paramount concern for health professionals, Fobair explained. The study was intended to fill in some of the unknowns about problems Hodgkin's patients face and to seek some solutions toward preventing the problems from developing.

A further study, funded by the American Cancer Society (California division), is now under way in collaboration with researchers at the University of California in Los Angeles, Fobair said, that should provide more detailed information.

The average age of the patients interviewed was 36, and their average elapsed time since treatment for the disease was nine years. Fifty-five percent of the subjects were male, and 45 percent were female.

At the time of their interviews, 82 percent of the patients were completely free of disease, 16 percent were free of disease but had recovered from a relapse, and two percent were undergoing relapse.

One measure of readjustment to society was employment status, the researchers noted. Finding work appeared to be less of a problem for men than for women, Fobair said. While 82 percent of the men were employed in full or part time jobs, 58 percent of the women were at work.

Overall, 71 percent of the patients interviewed found full or part time work. Of the unemployed individuals, only 5 percent were actively seeking jobs, she noted.

Most patients remained interested in the jobs they pursued. Eighty-one percent of patients reported continued motivation and ambition with respect to careers, the researchers found.

However, problems on the job were frequently reported by the recovered patients. Forty-two percent perceived discrimination or difficulties at work, the researchers learned. Major complaints included lack of promotions and job offers, conflicts with coworkers, and denial of insurance.

However, Fobair cautioned that because the study did not compare pre- and post-cancer employment patterns and because it did not include a comparision group of non-cancer patients in similar positions, it was difficult to evaluate whether or not the frequency of employment and of job-related problems was significantly different from normal.

Lack of energy was a problem for 90 percent of the patients while they were undergoing treatment. However, 60 percent had regained normal energy level one year beyond therapy. Younger patients experienced swifter recovery of energy than did older patients, Fobair noted.

Fobair identified depression as one of the most serious obstacles to full rehabiliation of the cured cancer patients. The researchers used a National Institute of Mental Health scale for rating severity of depression.

-more-

Although the pooled average score of all patients was within the normal range, 20 percent of patients had scores reflecting clinical depression. The mood disorder was more common in those 20-35 years of age than in younger patients. Depression was more frequent among patients recently diagnosed and treated and less frequent among those whose duration of follow-up was longer, Fobair reported.

Issues that may contribute to depression, Fobair said, include fear about loss of life, impaired body image, and fear of a recurrence of the cancer.

The researchers found a significant overlap among patients reporting depression and those who reported low energy level and low levels of sexual interest and activity, Fobair said.

Over two-thirds of the patients felt their general health was fair to excellent, while the rest felt their overall health was poor. Approximately three-quarters of the patients interviewed retained a positive body image while one-fourth felt the cancer and its treatment had impaired their body image, the researchers found. Body image decline reflected a sense of loss of general well-being, Fobair said, often associated with the patient's feeling that "my body let me down."

Nearly half of the patients who had been married at the time of their cancer diagnosis reported having divorced or separated since then. This divorce rate is comparable to the national average of failed marriages, which is about one out of two, Fobair said. Eight percent of all the divorced or separated individuals attributed their dissolution to problems connected with the illness, Fobair said.

Diminished sexual interest and activity was reported at approximately the same rate by women and men, and was a more frequent problem in individuals more than thirty years of age, the study showed. While fewer than 10 percent of men under 30 reported decreased sexuality, about one in four men over 30 reported a sexual decline. Approximately 10 percent of women under 30 experienced such sexual problems compared to one in four women over 30, Fobair said.

Family planning results parallelled findings from a previous Stanford study of fertility in Hodgkin's disease patients, which demonstrated that approximately 20 percent of women treated for the disease went on to bear children. In the current study, of those patients with children, approximately 25 percent had had them following their recovery from illness. Among those without children, one out of four reported they were unable to conceive.

Families and friends were by far the most frequent sources of emotional support for patients: 67 percent sought help from family and 48 percent turned to friends as well. Religion and the health profession also provided support for some.

Fobair said that as a result of the study, the psychosocial services program at Stanford is enlarging its scope through increased referrals for vocational help and psychotherapy. In addition, she said that a newsletter and a discussion group for Hodgkin's patients were recently initiated.

RESIDENTIAL THERAPEUTIC COMMUNITIES SUPERIOR FOR TREATMENT OF HEROIN ADDICTS, STUDY SHOWS

STANFORD—

Therapeutic residential communities are superior for treating heroin addicts than methadone treatment or outpatient psychotherapy, a Stanford University Medical Center study has found.

The authors of the study, published in the February 1984 *Archives of General Psychiatry*, are encouraging members of the medical profession to recognize the effectiveness of longterm inpatient treatment, and overcome their pessimism and reluctance to refer addicts to inpatient treatment facilities.

The number of addicts, the authors point out, has dramatically increased to constitute up to 2 percent of the U.S. population.

In their study, the researchers found that participants did change their drug use habits after longterm inpatient treatment. And, they went through a rehabilitation process that helped them enter the mainstream of society. Many were employed or enrolled in some type of educational program, and participants had far fewer arrests and convictions for crimes than before treatment.

Drs. Richard Bale and Vincent Zarcone of the department of psychiatry and behavioral sciences headed up the study comparing three types of inpatient treatment communities at the Veterans Administration Medical Center in Palo Alto and Menlo Park. The communities differed in their organizational structures, staff qualifications, and rules patients were obligated to follow.

In a two-year follow-up of the 363 addicts who participated in the study, the researchers were able to contact an unprecedented 96 percent. This compares with a 40-60 percent follow-up range of most previous similar studies.

The researchers measured the success of the programs by comparing—before and after treatment—the amount of heroin or other illicit drug use by the participants and the control group, the number of addicts either working or going to school, and the number of their arrests and convictions.

As many as 60 percent of participants in one of the three groups reported no heroin use for the three months preceeding the follow-up, as compared with about 33 percent of those from the control group who underwent only a five-day narcotic addiction withdrawal program. Nearly 57 percent of participants from one of the groups reported no other illegal drug use for the preceeding three months as well, compared with about 39 percent from the withdrawal group.

Nearly 68 percent of participants in one of the groups had no convictions since they began treatment, compared with only 31 percent of those from the withdrawal group. And almost 59 percent of one of the groups reported they were working or attending school, compared with 34 percent of those from the withdrawal group.

APRIL 12, 1984

-more-

"What this tells us is that the treatment of heroin is like that of alcohol. You don't get total abstinence more than about 25 percent of the time, but you do get substantial control up to about 70 percent of the time," Zarcone said.

But, he added, the participants did show much improvement in two "socially important variables. We had a high percentage of guys who were paying taxes and not committing crimes."

With funding from the National Institute on Drug Abuse, the researchers focused on three types of communities, established in the early 1970s following a federal mandate that all veterans returning from Vietnam with drug problems be treated.

The Family was a peer confrontation program, derived from the well-known Synanon. It was run by professionals and former patients, and its participants had very little contact outside the community. No drugs or alcohol were allowed for patients or staff. "The community strikes the visitor as very clean, organized, and regimented," the researchers wrote in the journal.

Quadrants, the second type of community, used a variety of therapeutic techniques, and was staffed by professionals and former patients. Participants had more contact with outsiders than those in The Family, and some drug and alcohol use was allowed. "The community strikes the visitor as quite loosely organized, with a good deal of freedom in personal appearance and expression," the report stated.

The final community, Satori, had more professionals and fewer patients on its staff. More emphasis was placed on individual therapy, and treatment included a comprehensive written program. Patients were allowed limited alcohol use off of hospital grounds, and had to undergo weekly urine tests to detect drug use. "The impression given by the program is that of a college dormitory during finals: busy, serious, and subdued," the researchers observed. Although all three groups have been extensively revised to be more effective-- they're much stricter now -- Satori was the more successful of the three groups, Zarcone concluded.

Participants were recruited for the study from 710 patients who entered the five-day inpatient narcotic addiction withdrawal program. The patients who wanted to get into a longer-term rehabilitation were allowed to choose any of the three communities. Those who underwent only the five-day withdrawal program served as a control group for the study.

"We may have compromised the study by not randomly assigning patients to nontreatment groups or to specific treatment groups," Zarcone explained. "We had to give the patients the choice however. Trying to do it any other way would be unethical."

"You cannot force or deny treatment for anybody," Bale added. "Not only is it unethical, but the patients' participation was voluntary. If they didn't get the treatment they wanted from us, they were free to leave and obtain it elsewhere."

And leaving, the scientists said, would amount to no treatment at all. Methadone maintenance, in which addicts are given the substance as a substitute to heroin in hopes of weaning them of their dependency, has been shown not to be effective, Bale said. Outpatient therapy, he continued, is not effective either.

-more-

"Many addicts' problems stem from their relationships with others," he explained. "These problems can't be addressed in therapy that takes place one hour each week because patients have powerful defenses they employ. Addicts also rarely are able to establish good rapport with authority figures. They respond much better to peers. The only way to address these problems is in a community where they can't hide or run away from their problems."

"We have patients who are coming back now five and ten years after their initial treatment who are raising families, employed, and doing great," Zarcone said. "These are people who were criminals when they came to the programs, completely strung out on heroin, not thinking about anything except where their next fix was going to come from. The effect of this type of change in lifestyle is important across generations."

"The concept of a therapeutic community is a very different kind of thinking than that of most medical professionals and medical consumers," Bale observed. "Physicians think they need to be able to handle anything on an outpatient basis, but in no way can they handle something like heroin addiction."

"Even with the great increase in the number of addicts, there is still an aura of not quite knowing what to do about treating them and not quite placing treatment in the mainstream of medicine," Zarcone added. "There's a lot of pessimism about the effectiveness of treatments. Physicians and medical students think there is not enough to learn about addicts and treatment, and what is known doesn't make any difference. Thus, lots of patients are going untreated.

"This study shows with some conviction that therapeutic communities can be effective," he said.

NEW LAW EMPOWERS INDIVIDUALS TO MAKE MEDICAL LIFE OR DEATH DECISIONS

STANFORD—

A new California law, the first of its kind, allows terminally-ill patients to designate another individual to make life or death decisions in the event the patient is unable to do so, said a Stanford University Medical Center physician.

The legislation, called the Durable Power of Attorney for Health Care, became effective Jan. 1, 1984. The agreement conveys the authority to consent, refuse, or withdraw consent "to any care, treatment, service or procedure to maintain, diagnose, or treat a physical or mental condition."

"This represents a dramatic step forward in this inherently difficult and highly emotional area of law and medicine. It also provides long overdue protections to health care providers who must implement these decisions," said Dr. Thomas Raffin, respiratory medicine specialist and assistant chief of medicine at Stanford Unversity Medical Center, and Michael Gilfix, former director of Senior Adults Legal Assistance of Palo Alto and San Jose. Gilfix has prepared a model of the document in accordance with the law that patients may sign.

The need for such legislation has surfaced in response to an increasing number of cases, such as the famous Karen Quinlan case, in which the court has become involved after decisions by family members to withdraw life support systems from patients who are terminally ill and often in a vegetative state.

"Many members of the legal and medical communities are of the view that the courts should have no role in so personal a decision-making process," Raffin said. "So serious is the problem that the mere filing of suit in any court of the country at any point in time has too often had a retarding and chilling effect on good judgment. Open discussion and common sense fall costly victim to this fear of controversy and litigation."

One of the most recent examples illustrating the need for the legislation involved two physicians in Southern California who withdrew life support systems from a comatose, terminal patient with permission from the spouse. Despite this, suit was filed against the physicians. "A legal roller coaster followed . . . . stressing the lack of reliable standards and decision-making methodologies that would eliminate the need for court involvement," Raffin said.

The legislation, introduced in the state senate about one year ago by Senator Barry Keene (Dem.-District 2), provides for a written document that can be signed by a competent adult naming another person "attorney in fact." This designated person then has the authority to make "virtually all medical care decisions for the adult if and when he lacks the capacity to make his own medical care decisions," Raffin explained.

The adult signing the agreement can "hand-tailor" it by specifying any types of treatment or placements he would not desire. The designated person is limited by the agreement only in that he "cannot consent to placement in a mental health treatment facility, to convulsive treatment, to psychosurgery, sterilization, or abortion," according to Raffin and Gilfix.

4-12-84

-more-

The agreement is good for seven years, or until the patient regains the capacity to make decisions for him or herself.

In conjunction with the new legislation, the California Civil Code has been revised to state that health care providers are not subject to "criminal prosecution, civil liability, or professional disciplinary action . . . . if they rely on a health care decision and both of the following requirements are satisfied." The requirements then listed refer to ensuring that the attorney in fact's decision was made in good faith, and that "the health care provider believes in good."

The new legislation is the third document available to medical care consumers in California that attempts to deal with the question of who has the authority to make life and death decisions. The Living Will is a document in which an individual can express his desire that extraordinary medical procedures not be used if he is terminally ill. It is distributed by Concern for Dying, a New York City-based organization. Having failed to hold up in Florida courts, "the living will remains a document of dubious legal reliability," Raffin said.

A "directive" of the California Natural Death Act, is the other document, providing "in essence" that in certain circumstances "life-sustaining procedures" may be withheld or withdrawn if a person is terminally ill. A number of requirements must be met to employ this legislation, but a physician can choose to ignore it without fear of being held liable. Because of this, the directive is not a binding document either, according to Raffin and Gilfix.

"The new legislation is a logical extension of the well-established principle that any competent adult has the right to refuse medical treatment," Raffin said. "It also eliminates cumbersome, costly and typically inappropriate intervention by the court system when difficult medical care decisions are to be made."

MEDICAL DECISIONS: WHO MAKES THEM?

STANFORD—

Medical decisions are becoming more complex and difficult to make in light of new legal, financial, technical, and ethical considerations present in today's health care delivery system, said Stanford physicians during a public lecture Tuesday (April 10) evening.

The lecture, called "Medical decision making: is it being taken away from you and your doctor?" was the last of a three-part series sponsored by Stanford University Medical Center for the community.

Today's physician/patient relationship attempts to involve the patient much more in the decision making process than in the past, according to Dr. Thomas Gonda, Stanford psychiatry department chairman, who described how such relationships have changed over time. But it is not always fair to expect the patient to be able to make health care decisions for themselves, said Dr. Robert Stebbins, a community internist.

New laws and court decisions setting precedents that require physicians to make patients equal partners in decision making present problems, Stebbins explained. "There is the difficulty of the patient having adequate medical knowledge and assessment ability to be able to make the best decision." And, he continued, many patients prefer to leave the decision making to the physician.

Insurance carriers and other 'nonmedical' parties have also become increasingly involved in decision making, Stebbins said, often limiting a physician's choices and possibly, the quality of care he is able to offer a patient.

This new trend has made physicians defensive in their medical practices, he added, and "nervous about our ability to satisfy our patients, where our primary responsibility lies, and the courts, where in times of trouble our patients will turn."

The courts' -- and government's -- involvement is especially evident in situations involving patients on life support systems in intensive care units, said respiratory specialist Dr. Thomas Raffin, assistant chief of medicine at Stanford. In recent years a number of cases in which physicians and/or families of patients who had "almost no chance to regain good quality of life" wanted to withdraw them from extraordinary life support have resulted in a judge deciding the patient's fate.

This trend is destructive, Raffin explained, and to avoid it people should make their opinions about how they'd like to be treated known before they happen to end up in intensive care.

While documents called The Living Will and the California Natural Death Act Directive are two ways in which a patient can make his desires known, neither have held up in court as legally binding for the patient or protective of the physician's liability, Raffin said. New California legislation, however, called the Durable Power of Attorney For Health Care, does provide for the first time legally binding documentation of a patient's desires for treatment or nontreatment.

4-12-84

-more-

Dr. Keith Marton of Stanford's department of medicine agreed that some of the ability to make decisions is being lost by physicians, but that's not necessarily bad, he said.

"We're now seeing medical decisions being made by people like administrators, insurance payers, legislators, judges and lawyers, as well as patients and providers," Marton said. "This is happening because the number of medical decisions being made today is so far greater than 20 years ago. This has to do with the increasing complexity of medicine, and the increasing number of alternatives made possible by advances in research and technology."

But because of the influence of nonmedical people now involved in decision making, physicians are being forced to look more closely at the care they're giving, Marton explained.

Physicians are paying more attention to the benefits of medical care, and to what their patients really want to gain from it, he said. They're tailoring technology usage to those patients who will have the most benefit. Physicians are looking at the process of decision making, he continued, and rather than focusing their efforts on gathering a magnitude of facts, they're focusing on what to do with those facts.

"We're seeing a new trend in medicine where we're beginning to understand our technology and to manage it to our own ends rather than allowing it to manage us," Marton concluded. "The overall quality of medical care can be made better without increasing the cost. There are still plenty of arguments to be had, especially in the ethical arena where there is no right or wrong answer. In the meantime, I'm looking forward to how the practice of medicine will change in the coming years."

"LIFE FLIGHT" EMERGENCY HELICOPTER BEGINS SERVICE MAY 1

STANFORD—

(Editors, news directors, reporters: Members of the media are welcome to attend the briefing and demonstration at the helipad at Santa Clara Valley Medical Center, 731 Bascom Ave., San Jose at 10 a.m., Friday, April 13. Safety procedures will be demonstrated to emergency department personnel, and Dr. Michael Eliastam, local Life Flight program director and chief of emergency services at Stanford, and medical staff from SCVMC, will discuss the new program. Life Flight crew members will be available on request for interviews and photo opportunities with the helicopter and on-board emergency equipment.)

A helicopter emergency transport system capable of dramatically slashing response times to the scene of emergencies will begin service May 1 under the auspices of two key Peninsula/south Bay medical centers.

A demonstration of the "Life Flight" program, sponsored jointly by Stanford University Hospital (SUH) and Santa Clara Valley Medical Center (SCVMC), has been scheduled for emergency department personnel, Friday, April 13 at 10 a.m. at the SCVMC helipad.

"Getting seriously injured or ill patients to the proper medical facility in optimum time is the goal of Life Flight," which will serve a 150-mile radius around both SCVMC and Stanford, said Michael Eliastam, local Life Flight program director and chief of emergency services at SUH. Life Flight is a trademark used by approximately 21 hospital-based emergency helicopter transport services nationwide.

"This is the first time that Bay Area residents will have a hospital-based helicopter emergency trauma service system," said Robert Sillen, executive director of SCVMC.

"The helicopter will be airborne within five minutes of a request.

"Once the patient is on board, the crew—including an emergency care physician and a flight rse—will be able to provide care equal to that available in an emergency room while the patient is heading to the hospital at 140 miles an hour," Eliastam said.

APRIL 12, 1984

-more-

2-2-2 Sillen said rescue time for patients in some isolated communities or remote sites in Santa Clara and neighboring counties can be reduced from more than two hours by ground ambulance to 30 minutes or less by helicopter.

"And the time is even faster if you consider that physician-led health care begins as soon as the helicopter touches down," Sillen said.

He cited Pacheco Pass, where serious accidents often occur on a dangerous stretch of Highway 152 southeast of San Jose, as an example of a location where the helicopter could provide far more rapid response than ground ambulance. In certain remote mountain or coastal areas, the helicopter can land in areas completely inaccessible to ground ambulances, he said.

Eliastam said recent academic studies have shown that the speed provided by air ambulance service clearly can result in saving lives and avoiding permanent damage.

Life Flight, based alternately at SCVMC's and SUH's helipads, will be available to fly patients from emergency scenes to any hospital with a licensed helipad in Northern California where appropriate care may be provided.

The service will also transport patients on request from emergency rooms throughout the area to specialized care, such as a spinal cord injury or burn center available at SCVMC, and other advanced care at Stanford, Eliastam said.

In addition to its ambulance service, Life Flight medical personnel will be able to respond to quickly to major disasters such as earthquakes to set up a field emergency hospital.

"Life Flight service may be especially crucial after disasters where road access to the scene may have been impaired or where the emergency is so widespread that health care in a local area may have been put out of service, Eliastam said.

Both Eliastam and Sillen emphasized that Life Flight is intended to supplement, not replace, existing ambulance and paramedic services.

The initial helicopter will be a French Allouette III, but this unit will be replaced within three months by a German-built MBB BK-105 CBS. The equipment is being leased by Rocky Mountain Helicopter Services Inc. of Provo, Utah.

The chief flight nurse is Marcia Katz, a five-year veteran in the helicopter emergency transport field. Two fulltime pilots and a fulltime mechanic have been employed.

Life Flight is linked to the inter-agency Emergency Medical System and may be summoned by any physician, hospital, police or fire department staff, industrial safety officer or authorized government or emergency agency personnel.

"Both Santa Clara Valley Medical Center and Stanford offer advanced trauma care for acutely ill patients," Sillen said. "Together, Stanford and SCVMC can draw upon their longstanding affiliation (including SCVMC's use of Stanford faculty physicians and housestaff) to present a solid partnership and strong base from which patients within and outside the county will benefit."

Before service formally begins May 1, the crew is conducting training flights throughout the Bay Area.

SYMPOSIUM SLATED ON MOLECULAR AND GENETIC MEDICINE FRIDAY MAY 4

STANFORD—

Genes that play a role in cancer (oncogenes) and proteins involved in the brain's electrical activity will be among the topics discussed at an all-day scientific symposium Friday, May 4 at Stanford University School of Medicine.

The symposium, "Perspectives in Molecular and Genetic Medicine," will begin at 8:45 a.m. in Fairchild Auditorium.

It is he second of a series of annual meetings at Stanford linked to the medical school's new program in molecular and genetic medicine, according to dean Dominick P. Purpura.

The program in molecular and genetic medicine, involving faculty from both the basic and clinical sciences, provides a scientific and intellectual framework to help rapidly translate research advances into new methods of diagnosis and therapy of human disease, Purpura said.

The symposium features presentations by prominent scientists from around the country, with introductions by Purpura, Stanford University president Donald Kennedy, and medical school faculty members.

A sample of speakers and their topics includes:

- Dr. Charles Stevens of Yale, on "Properties of Proteins Responsible for the Brain's Electrical Activity"
- Dr. Thomas Maniatis of Harvard, on "Molecular Genetics of Human Globin Gene Expression"
- Dr. Mariano Barbacid of the Frederick Cancer Research Center, on "Oncogenes in Humans and Experimentally Induced Tumors"

Other speakers come from the University of Washington, Rockefeller University, and the Carnegie Institution of Washington.

The symposium is open to invited guests and faculty, students, fellows, interns, residents, and staff.

Copies of the program can be obtained from the Office of Public Events, Stanford University School of Medicine, 750 Welch Road, Suite 300, (415) 497-6389.

HOW PARENTS COPED WITH DAUGHTER'S MYSTERIOUS DISEASE

STANFORD—

Only last month, Evelyn and Gene Rose feared that their daughter, Jessica, might die. But today they marvel that she looks so healthy.

The rare illness one-month-old Jessica contracted is called infant botulism. Though it caused extensive paralysis, Jessica is steadily regaining movement throughout her body, and doctors say she should have no long-term effects from the disease.

Infant botulism affects only a tiny number of babies, almost always under one year of age. But recently, for unknown reasons, its incidence in California has risen to five times its normal rate. Twenty cases have been reported so far in 1984, according to the California Department of Health Services.

The disease is caused by a bacterium, *Clostridium botulinum*, which in a few cases grows in the intestine and produces a paralyzing poison. At its worst the disease can cause extreme breathing difficulties and inability to swallow, but it seldom leads to death. Scientists don't yet understand the disease completely, and its only treatment is with supportive measures and careful monitoring. Because it is so rare, doctors often aren't familiar enough with infant botulism to recognize it.

Ironically, the first symptom of Jessica's illness seemed minor, her mother Evelyn recalls. "About two weeks before it actually set in, she was constipated. But, being a new mother, I wasn't even sure it was constipation," she says. Absence or infrequency of bowel movements is often the first sign of the disease's paralyzing effect, explains Dr. Barry Tharp, the Stanford pediatric neurologist who diagnosed Jessica's illness.

The bacterial spores are commonly found in soil. Older children, adults, and even some young infants ingest the ubiquitous bacteria with no ill effects. Only in a small number of infant cases does the bacteria cause disease, excreting the same dangerous toxin that, in a jar of badly canned vegetables, can cause botulism and even death in an older person.

Why botulism bacteria thrive and produce toxin only in a few babies is still in question, Tharp says. But its effect on these infants is profound, he says. It interferes with the normal release of the chemical messenger acetylcholine at the junction of nerve and muscle, causing paralysis.

For Jessica, as with most children who get infant botulism, constipation only hinted at what was to come. Gradually, says her mother, "she started having trouble eating. In 24 hours, I couldn't get two ounces of formula down her. She got so she was sleeping 'round the clock. She was limp, and she couldn't move her head."

4-9-84

-more-

Evelyn told Jessica's doctor about the changes in her daughter. "He said if she didn't eat through the night, we'd have to take her to the hospital."

The following morning, Jessica became critically ill, choking, gagging, and unable to swallow. By the time she entered the local community hospital later that morning, she was pale and having trouble breathing.

Doctors could not pinpoint the cause of Jessica's symptoms, her father, Gene, recalls, but tested her for meningitis, an inflammation of the lining of the brain.

When antibiotic treatment failed to help, doctors suggested that infant botulism might be the culprit. Because she might need specialized care, the local doctors decided to send her to Stanford Hospital's pediatric intensive care unit. Most infants with the disease must be placed on respirators to aid breathing. Though Jessica was lucky enough to have a milder case, she still required tube feeding to prevent fluid from entering her lungs, a potential cause of pneumonia.

The difficulty with infant botulism, says Tharp, is that there is no known drug therapy for it. The only course of action for the disease is to constantly monitor and support vital functions until the baby recuperates.

Honey has been suggested as a common source of the bacterial spores. Avoiding giving honey to infants is prudent, Tharp says, but the connection is established only in a few cases. Jessica was not given honey, and doctors don't know exactly how she ingested the bacteria. But botulism spores can easily travel airborne into a baby's environment for ingestion.

Now that Jessica is recovering, her parents say that looking back, the hardest day was when their doctor had Jessica transferred by ambulance to the pediatric intensive care unit at Stanford University Hospital.

"The first day was terrifying. You see nurses rushing around, putting things in her. You don't know what's going on, and you see all the other babies in there who look as bad as she did, and you think—that's a room for the dying," says Evelyn.

Gradually, though, Jessica began to improve and was moved to the regular pediatric unit. She began to regain some arm and leg movement, as well as her skin color and ability to cry. As her swallowing ability returned, her mother began to give her regular bottle feedings, each time increasing the amount of formula.

Just a few days ago, Jessica went home well again.

WEIGHT CONTROL PROGRAM BEGINS NEXT MONTH AT STANFORD HOSPITAL

STANFORD—

An eight-week course on weight control, to be conducted by registered dietitians at Stanford University Hospital, will take place May 8 to June 26.

Titled "An Enlightening Experience," the course is open to the public and will be held Tuesday evenings at the Hoover Nursing Cottage, located in a hospital annex across from Stanford Shopping Center.

Highlights of the program include a personalized weight loss plan, low calorie cooking demonstrations and recipes, menu planning, and tips on dining out wisely. Guest speakers will discuss stress reduction, behavior modification techniques, and exercise.

Kristine Birge and Patricia Kearney, dietitians from the hospital's department of dietetics, will conduct the classes.

Enrollment is limited to 20 participants. The deadline to register is April 24, and early registration is advised. A fee is charged. Future series are planned for September and January.

For more information, call Birge at (415) 497-5440.

COMPETITION: A NEW INGREDIENT IN MEDICAL CARE

STANFORD—

Rapidly rising costs have injected competition—the American way—into the U.S. health care system, two hospital administrators and the benefits manager of a major corporation acknowledged Tuesday (April 3) during a public lecture at Stanford University Medical Center.

While there are both pros and cons to the newly competitive atmosphere among health care providers, mostly there are great adjustments to make. "Unlike other industries where usually the customer reigns supreme, we are accustomed to defining our own quality," said Dr. Rod Aymond, chief executive officer at O'Connor Hospital, San Jose.

"But now doctors and hospitals are being told by insurers, government and large buyers of health care packages, 'You will receive X dollars, and we wish you to provide all the care needed for the people we cover'," added Sheldon King, director of Stanford University Hospital.

"This requires some very tough decisions," he said. "For one thing, our love affair with technology must come to a close. We'll have to introduce new technologies more slowly. The health care industry must get smaller."

One important measure hospitals will take, King said, is to end too much overlapping of services. "There must be a recognition that certain procedures can best be performed in one center over another.

"Competition will lead to not all hospitals doing the same things, and a common knowledge about where to go for what," he said.

"Patients are becoming much more aggressive about determining their own treatment," said Aymond. "We have to respond to that. Patients are no longer a captive group; they *can* walk. Many know more today about their bodies and their health needs, and government and corporate measures have aimed to shift the financial risks from the payor to the payee."

An example of such a system, he said, are Diagnostic-Related Groups, or DRGs, which insist that payments be determined prospectively for reimbursement purposes.

Art Young, corporate benefits manager at Hewlett-Packard (HP), stressed that his company emphasizes health promotion and awareness among employees, so that people begin to take more responsibility for their own health.

4-4-84

-more-

HP spends about $1,300 per worker per year for health care currently, he said. That means employees may not get certain other benefits such as child care or profit sharing. With health care costs rising faster than most companies' profits, "there's a lot of scrambling, cutting of benefits, and requiring higher copayments and deductibles in the corporate world now," Young said.

HP developed a strategy to face the financial crunch, Young said, first by determining exactly where the health care dollar was going. "We found several interesting trends. For example, the average length of hospital stay was shorter under health maintenance organization (HMO) coverage than under private insurance. Also, certain procedures were being covered more generously and expensively in the hospital than on an outpatient basis.

"Some people with working spouses were being over-reimbursed. We're now trying to coordinate benefits better, so that each spouse's insurance pays for part, not all, of the costs."

HP is also piloting a pre-paid drug payment plan for retirees, Young said, in which generic forms of medications are predominantly used. "We have to look very carefully at how we can best cover retirees, as well as whether to cover such things as home health care or hospice care," he added.

"We have observed one fundamental change: we're beginning to act like buyers of health care, instead of like payers. That's true of HP specifically, and I'd say of companies in general," Young noted.

One questioner in the audience wanted to know if it's true that the patients—the consumers—are still the ones left out in the cold, with power simply shifting from the hospitals and doctors to the corporations, insurance companies, and government.

"At this point we offer options to our employees, including some HMO plans," Young said. "We're shifting our emphasis to coverage for catastrophic care, generally." HP recently signed a contract with El Camino Hospital for employee care.

How hospitals deal with escalating costs will depend to a large extent on better communication between administrators and doctors, all three speakers agreed.

"We're moving toward a more conservative form of medical practice with a reduced amount of ordering for expensive tests and technology," King said. "We must get away from defensive medicine."

Other sources of possible cost reduction in hospitals include cutting non-patient areas first, as well as certain rarely used services, maintaining staffing flexibility, using volunteers more efficiently, standardizing equipment, and seeking better ways to report data.

"But in regard to reducing the aggregate cost of health care, we're really part of a giant social movement that we're not in control of," Aymond said.

"We live in a time of limited resources," King agreed, "just as we know we'll run out of oil eventually."

Teaching hospitals face unique concerns, he said, because they are more likely to focus on tertiary care—that of the sickest referral patients—while having to work with medical schools to remain on "the cutting edge of medicine." Also, care of the indigent tends to become the responsibility of teaching hospitals.

-more-

"Then, we in a sense create our own competition," King said, "when we export—though not inappropriately—our expertise to other hospitals."

King said referrals to Stanford Hospital had been dropping off recently, "probably because patient census has gone down everywhere and hospitals are retaining patients they would have referred to Stanford in the past."

Entrepreneurs have entered the health care scene, Aymond noted, taking up issues traditionally handled by hospitals. "Clinics and centers, for this and that, are popping up wherever there's profit in sight," he said.

"Hospitals are doing this too, in the form of satellite programs and outreach programs in the community. That's necessary, both because it's less expensive outside hospital walls, and because you want people to think of your hospital when they seek care. Without outreach, the highest costs become concentrated inside the hospital."

Hospitals today are using their profitable services and even outside ventures to boost their other operations. Another important step would be to improve criteria for moving patients effectively out of the most intensive care facilities and into general units.

"If we can reduce the average length of stay by half a day," Aymond said, "that will be quite a huge savings compared with reducing labor costs."

Aymond and King predicted that many hospitals will have to close in the next few years, and that that will save the entire health care industry a lot of money.

"There seems to be a social consensus that costs are too high now and must go down," Aymond said, "and that's much of what prompted the new competition.

"But there are still important questions to be dealt with, like what will happen to the disadvantaged or the terminally ill, and what will happen when equipment ages and there's not enough capital to replace it. People underestimate how much unreimbursed care hospitals deliver."

The big question society must answer, the speakers agreed, is what are the essentials of health care.

The evening's program was moderated by Dr. Michael Eliastam, assistant professor of surgery and medicine, and director of emergency services at Stanford Hospital.

Next Tuesday's public lecture, the last of the Progress in Medicine series on Health Care in Crisis: Questions of Cost and Quality, will be held 7:30 p.m. April 10, in the Fairchild Auditorium of the medical center. Moderated by Dr. Thomas Gonda, professor and chairman of psychiatry, it is entitled "Medical Decision Making: Is it being Taken Away from You and Your Doctor?"

CANCER RESEARCH MOVES AHEAD WTIH GRANT SUPPORT

Photos of Rosenberg available upon request.

STANFORD—

Research scientists at Stanford University School of Medicine are testing some of the newest diagnostic techniques and treatments for cancers of the lymphatic system under a $1.3 million grant from the National Cancer Institute (NCI).

The three-year grant was renewed for its second year effective April 1.

Techniques being tested include the use of anticancer drugs and radiotherapy, genetically engineered monoclonal antibodies, the natural antiviral substance, interferon, and bone marrow transplantation.

Headed by Dr. Saul Rosenberg, professor of medicine and radiology and chief of the division of oncology, the project brings together both clinical trials and laboratory studies in an effort to improve the treatment of patients with all types of human malignant lymphomas.

"Previously, for about 20 years under the direction of the late Henry S. Kaplan, we'd been conducting clinical trials directed toward many types of cancer," Rosenberg explained. "But it became clear that we were focused on Hodgkin's and non-Hodgkin's lymphomas, whose treatments have been improved dramatically."

The current project carries on the interdisciplinary nature of the research, Rosenberg said, and brings it even further into the basic science lab.

A team of oncologists, pathologists, immunologists, statisticians, radiologists, nurses, pediatricians, dermatologists, and others intend to study the biology of human lymphoma cells, improve the cure rate while decreasing the toxicity of current therapy for lymphoma, and develop new modalities of treatment.

All experimental treatment protocols, Rosenberg stressed, are designed to be at least as good as the best established treatment available.

-more-

4-3-84

Lymphomas are tumors of the lymphoid tissue which contains lymphocytes, the white blood cells of the body's immune system. Some types of lymphocytes make antibodies. One offspring of the current project has been carried out by Dr. Roger Warnke, associate professor of pathology, who has determined how to classify types of lymphomas by using different types of antibodies as immunologic markers.

Meanwhile, Dr. Jeffrey Sklar, assistant professor of pathology, has studied the specific genes that are responsible for the antibodies produced. Thus, lymphomas can be classified by looking at DNA arrangements (like fingerprints), as well as by searching for the protein product or antibody.

The work of Dr. Ronald Levy, associate professor of medicine, with genetically engineered monoclonal antibodies—special proteins that can seek and destroy cancer cells in the body without damaging healthy tissue—facilitates investigation of their potential therapeutic value, Rosenberg said.

Trials of interferon supported by a companion NCI grant, and conducted primarily by Dr. Sandra Horning, assistant professor of medicine, suggest it's a protein with anti-growth and cancer "watchdog" properties which might help prevent relapse in patients who've been treated successfully with conventional methods.

Limited trials of bone marrow transplantation, performed through a cooperative arrangement with the University of Washington, are at this point aimed only at patients who are not able to be helped or cured in other ways, Rosenberg said.

Rosenberg emphasized that all collaborators on the project serve as both resources and as independent investigators. And the patients, certainly, play a vital role, supplying biopsy specimens of tissue and other samples to academic labs while participating in large numbers, with informed consent and at minimal cost, in the clinical trials.

"The results of our ongoing clinical trials are used to design new protocols, mostly testing various combinations of radiotherapy and chemotherapy," Rosenberg explained. "Outcome data are accumulated and analyzed in terms of response rate and cure, with special attention to the long-term morbidity of treatment."

STANFORD--

DOCTORS REVEAL RISKS OF ANESTHETIC AND SEDATIVE DRUG

An effective new anesthetic and sedative drug has potentially hazardous side effects, Stanford physicians warned in an article in the May 31 issue of the *New England Journal of Medicine*.

The drug, called etomidate, can block the adrenal gland's production of cortisol and other important steroid hormones, possibly leading to temporary adrenal gland failure, the doctors said.

This may cause abnormal salt and water balance, lowered blood pressure, and ultimately shock, the researchers added.

But if patients are given doses of the suppressed steroid hormones along with the drug, they may be protected from these potentially harmful side effects, the researchers suggested.

The study of etomidate was conducted by Drs. R. Lee Wagner, Paul F. White, Patricia Kan, Myer Rosenthal, and David Feldman from the departments of anesthesia and medicine at Stanford University School of Medicine. The research was supported in part by grants from the National Institutes of Health, and from the anesthesia department at Stanford.

"Until the clinical implications of these findings are clarified, we think that physicians should be aware of this side effect of the drug and be prepared to treat postoperative or critically ill patients with corticosteroid supplementation," the researchers wrote.

Etomidate has been in widespread use in the United States only since 1983 although it was introduced in Europe 10 years earlier. It has gained wide acceptance as an anesthetic in cardiovascular surgery and is also effective for sedating patients receiving breathing support, White said.

Last year several publications from England reported a higher than average death rate among intensive care patients sedated with the drug on a long-term basis, Feldman said.

The patients who died were found to have low levels of cortisol, a steroid hormone produced by the adrenal gland to help the body overcome stress. Without enough of this hormone a person's blood pressure can fall to dangerous levels, White explained.

"In retrospect, the use of etomidate on a long-term basis may have contributed to this problem," White added.

Patients who receive etomidate as an anesthetic in the operating room probably have less risk of harm, White said, because enough hormone is present in the body to last through the few hours required for surgery. Probably, patients would only be at risk if subjected to unexpected stress, such as infection or bleeding, during the early postoperative period, White added.

In contrast, in intensive care patients on prolonged sedative therapy the hormones could be depleted, leading to potentially greater risk of complication, he suggested.

Feldman, White, and their colleagues studied five patients who received etomidate, four during cardiovascular surgery and one in intensive care. Cortisol levels fell in all five patients, with a more lasting effect in the intensive care patient who received the drug for 20 hours. All five patients also had depressed levels of aldosterone, an adrenal steroid hormone that helps maintain normal balances of water, various salts, and blood pressure in the body.

The researchers also found, at the molecular level, how the drug inhibits the body's production of the adrenal steroid hormones, Feldman said. In rats, they found that etomidate inactivates two enzymes that catalyze production of a group of steroids, including cortisol, aldosterone, and various sex hormones.

"Although dire consequences are rare during routine operations, we feel the medical community should be alerted to their possibility," the researchers said.

"Further studies are necessary to ascertain whether the risks of adrenal suppression outweigh the benefits of this otherwise useful anesthetic agent," they concluded.

Several additional studies are currently under way, White noted. —30— LH3

SPEAKER TO HIGHLIGHT MEDICINE IN ECUADOR

STANFORD—

Tom Brown, M.D., a Salesian priest, will give a public lecture on "Medical Practice in the Upper Amazon Valley" at 11 a.m., Monday, June 4, in Schultz Auditorium at Stanford.

Brown will focus on the medical and management problems—as well as the philosophy and ethics—of running the hospital he founded in Taisha, Ecuador, to serve the Shuar and Achuar American Indians.

Brown was raised and educated in the United States. Although trained as a pediatrician, he treats all ages at his Taisha hospital.

The talk is sponsored by Stanford's division of family medicine of the department of family, community and preventive medicine. For more information, call Penny Thorpe at 497-7063.

The auditorium is located in the Health, Research and Policy Building (behind the museum) at Stanford University.

SYMPOSIUM TO FOCUS ON ISSUES INVOLVED IN CRITICAL ILLNESS

STANFORD—

Morris Abram, vice chairman of the United States Commission on Civil Rights, the Rev. Benedic Ashley, moral theology professor and author, and Victor Fuchs, noted health care economist will be featured at a symposium entitled "The Doctor's Dilemma Revisited: How Much Care and at What Moral Cost?" at Stanford University Medical Center June 9, 1984.

The symposium, sponsored by the Stanford University School of Medicine and the Stanford Medical Alumni Association as part of an annual alumni event, is open to the public.

Other speakers will be Dr. Thomas Raffin, assistant professor and assistant chief of medicine, and Michael Gilfix, Palo Alto attorney specializing in medical legal issues and "elder law."

Topics will include medical decision making in withdrawing life support for terminal patients, the rationing of medical care, ethical decision making in critical care, and the legal side of preparing for critical illness. Abram's keynote address is entitled "Critical Illness: Where Science, Morality, Theology, and the Law Intersect".

The symposium will be followed by the alumni association's annual business meeting. Reunion dinners are planned for the classes of '34,'39, '44, '49, '54, '59, '64, and '69.

The symposium will take place in Sherman Fairchild Auditorium at the medical center, starting at 8:15 a.m. For more information call (415)-497-5064.

NEW ASSOCIATE HOSPITAL DIRECTOR APPOINTED

STANFORD—

Gerald R. Moller has been appointed an associate director of Stanford University Hospital (SUH) with primary responsibility for the Hospital Modernization Project, Facilities and Operations, and Maintenance divisions of the hospital.

Sheldon S. King, director and executive vice president of SUH, said Tuesday (May 29) that the appointment to the newly created associate directorship represents the first in a series of top level organizational changes.

This "is a major assignment and should go far towards coordinating the activities of the Medical Center," King said in a appointment letter. For the first time, King said, the hospital's major engineering and construction management functions are consolidated under the leadership of a single associate director.

King said additional senior management and related organizational changes would be announced as soon as they are finalized in the near future. Currently, including the new appointee, there are five associate and one senior associate director reporting to King.

Moller, 58, served since October 1982 as deputy director of the modernization plan, a five-year, $110 million project intended to consolidate and improve SUH facilities and facilitate moving Children's Hospital at Stanford from its current Willow Road site to a new building adjacent to SUH.

The new associate director came to Stanford from a position as associate administrator at Children's Hospital of San Francisco, where his varied duties included responsibility for building projects. He had served at that facility in various capacities since 1949.

Moller holds a B.S. in engineering from the U.S. Merchant Marine Academy.

FRIENDS OF NURSING FAIR SCHEDULED AT SHOPPING CENTER

STANFORD—

The public may ask a nurse (or dietitian) for advice on cancer detection, back and neck care, reconstructive surgery, skin care, nutrition and six other general topics at a health fair scheduled Saturday June 2 from 10 a.m. to 4 p.m. at Stanford Shopping Center Pavilion.

Among free services available to the public will be free blood pressure checks, head and feet massages, and a variety of educational literature. Several booths feature teaching videos.

"It is in the best self-interest of the public to take control and charge of their own health care, especially now as such costs are escalating," said Leona Hansen-Nealey, president of Friends of Nursing, the organization sponsoring the event.

"Nurses are offering their time through Friends of Nursing to provide one-on-one demonstrations and answer individual questions," she said.

Additional topics include information and safety guidance on commonly used medications and safety, stress and mental health, the Visiting Nurses Association and home health care, addictive substances, and sex and sexually transmitted disease awareness.

Another booth will provide information on Friends of Nursing, a Stanford Medical Center-sponsored group of nursing and community volunteers who support nursing activities and provide information on the modern role of nurses.

Chairman of the event is Patricia Tharp, staff nurse in Stanford University Hospital's cardiac surgery intensive care unit.

COMMUNITY INVITED TO HEAR GUEST LECTURE AT MEDICAL SCHOOL

STANFORD—

Dr. Christopher S. Wilcox, assistant professor of medicine at Harvard Medical School, will present the sixth Pfizer Lecture in Clinical Pharmacology at 5:15 p.m. Thursday, May 31, in room M110 at the School of Medicine. The public is invited.

In his lecture, titled 'Tubular-Vascular Integration in the Kidney: Roles of Angiotensin and Prostaglandins,' Wilcox will summarize his research findings on how these substances affect renal function.

Educated in England, Wilcox holds both medical and Ph.D. degrees. He is a leading authority on the role of kidney physiology in the cause and treatment of high blood pressure and is noted for research on a number of related subjects, including the effect of diuretics and sodium balance on hypertension and the effect of antihypertension drugs on angiotensin.

The Pfizer Lectureship, started in 1978, is sponsored by Stanford's division of clinical pharmacology and funded by Pfizer Pharmaceutical, Pfizer Inc. of New York.

ALCOHOLICS NEED TO UNDERSTAND SOME PROBLEMS ARE BIOLOGICAL, PSYCHIATRIST SAYS

STANFORD—

Alcoholics can recover more easily if counselors reassure them that some of their post-drinking problems are biological, not social, a psychiatrist says.

Dr. Robert Landeen, medical director of the inpatient psychiatric unit at Stanford University Hospital, said at a public lecture Thursday (May 24) that certain problems—such as impotency, weight gain or even sensitivity to light—may be common to alcoholics who have been sober for periods of a few months to a year.

"There are specific factors that a fair number of people have during the recovery process that are largely independent of psychological and social factors," Landeen said in the third of four lectures sponsored by the clinic.

For example, Landeen said a survey he and colleagues conducted several years ago among 53 recovering alcoholics showed that 31 percent of the males suffered impotency, 25 percent of the sample suffered lower rib area aches, and 63 percent showed an increase in weight and appetite.

While some of these and other conditions included in the survey are more health threatening than others, Landeen said it is helpful and reassuring to the recovering alcoholic to recognize that a variety of conditions may be normal.

"It's important to recognize these signs so we can impart a great deal of confidence in the recovering alcoholic. (We need to do more than) just say, 'you're going to feel better and things are going to get better.'

"For example, the first one or two weeks of recovery, sleep is a horrendous problem." Landeen said some persons slip back into drinking at this time just to go to sleep, while others seek sleeping medication, thus developing a new dependency.

But by recognizing that the sleeplessness is normal, patients can be counseled to survive through the difficult few weeks, Landeen explained.

The psychiatrist said he finds it "clinically useful, for example, to point out to a recovering male alcoholic who is impotency, that 'fine, that's expected.' A fair amount of recovering male alcohoics have that, so don't worry about it right now.'" If the problem persists beyond about six months, it can be discuseed later.

In many cases, Landeen said, patients can be reassured "to hang in there" if a counselor can document that the condition is ordinarily temporary.

". . . I know it's a passing phase and I can impart that to him."

The recovering alcoholics surveyed by Landeen and colleagues came from a variety of treatment programs. All of those surveyed had been free alcohol for periods of several weeks to one year.

A few other common biological conditions reported by the survey group included motion dizziness, 19 percent; sensitive to night lights (such as an oncoming car's headlights), 30 percent; and a craving for sugar, 43 percent.

When similar questions were posed to non-alcoholics, the percentage of persons reporting the same conditions was radically different, Landeen explained. His findings have been presented at a meeting of the National Council on Alcoholism.

Robin Press, a psychologist with the Stanford Alcohol Clinic, will discuss "Cocaine, The New High," the final free lecture in the series, Thursday, May 31, at 7:30 p.m., room M104 of the Stanford Medical School.

STANFORD LEGACY RECEIVES AWARD

STANFORD—

Of all he's done since he first entered Stanford University as an undergraduate in 1926, Dr. David Rytand notes two achievements he considers his greatest. "I taught students, and I listened to patients," he says.

Colleagues describe Rytand's 58-year-long association with Stanford a bit more glowingly. Stanford Medical School ombudsman Dr. Allen Barbour says Rytand has "achieved 'legend-in-his-own-time' status." That legend has now been enhanced even more: Rytand is the recipient of the 1984 Albion Walter Hewlett Award.

"The criteria to receive the Hewlett Award are to have acted like I think a doctor should act," Rytand says. "And over the years, that's what I've tried to do."

The award, established in 1983 by Stanford University Medical School's department of medicine, honors academic physicians who excel in their scientific knowledge and application of it to patient care. It is in memory of Hewlett, an internationally known professor of medicine and leader in clinical investigation at Stanford until his death in 1925.

Rytand is scheduled to be presented with the award, which includes a certificate, specially designed bookplates, and a silver medallion depicting figures from the metal sculpture representing the award, at the department's grand rounds Thursday (May 31) at 8:30 a.m. in Fairchild Auditorium.

In return, Rytand plans to present the medical school with his newly published book, "Medicine and the Stanford University School of Medicine circa 1932: The Way It Was." "It's a vignette—a picture of a spot in time," he explains. "I just wanted to tell what Stanford and the medical profession was like when I went through medical school and was on housestaff."

Indeed, Rytand fondly recalls the days he spent in San Francisco at "the old school." Sitting at the huge antique oak desk in the office that he, in his current position as director of medical school alumni relations, shares with the medical school ombudsman, his eyes sparkle as he puffs on his ever-present, aromatic pipe and talks about "the good old days," and his medical career.

Stanford was a "fun" place, Rytand says. In his book he tells about the expected dress of slacks, tie and coat, the all male classes, about the professors' sternness, the lack of almost any social life, the limited base of medical knowledge and clinical techniques, and the total committment essential to learn to be a doctor.

-more-

5-25-84

In the midst of it all, Rytand apparently thrived."Rytand was in the top of his class," recalls former classmate and colleague Dr. Roy Cohn.

After receiving his medical degree in 1933, he stayed on at Stanford and moved up the professorial ranks, and served as chairman of the department of medicine from 1954 to 1960, during which time the medical school moved down to the Stanford campus. "Those were difficult years," he recalls, "when all the decisions were being made. Everyone got 'committeed out'. One day I went into a room and sat down for a committee meeting. I must have been there about 30 minutes before it dawned on me that that wasn't where I was supposed to be."

In 1958 Rytand became the first Arthur L. Bloomfield Professor of Medicine, the first endowed chair in the department of medicine. He has received numerous awards throughout the years for his contributions to medicine and to medical education. In fact, as chief of cardiology at Santa Clara Valley Medical Center since 1975, Rytand was honored by having the electrocardiographic laboratory named after him.

Although teaching and seeing patients were always his foremost objective, he says, Rytand delved into research as well. When he started out, he says, "research was more of a hobby which we did at almost no expenditure of money on evenings and weekends for fun. Research was like a game. If you had the time you went ahead and played at it."

Rytand "played at it," and came up with some interesting findings. The "most practical" finding, he says, came about in the early 1950s when he discovered that vitamin K, found in high quantities in food supplement, neutralized the effect of anticoagulant medications, given to heart attack patients. Today, he proudly points out, the level of vitamin K in food supplements has been reduced to almost nil.

In 1946 Rytand described a unique late diastolic murmur associated with heart block, which he had observed in some of his patients. And his work with atrial flutter, which he says he still has to finish up, has given credibility to the once-doubted circus movement theory, which explains why the heart beats irregularly in certain heart disorders.

Rytand got involved with the medical alumni association "by accident" in 1964, and has played an integral role since. As director of alumni relations, to which he was appointed in 1981, he is a "trouble shooter" between alumni and the medical school.

"The alumni think highly of him, as did his students and patients," Cohn says.

"He has had a profound influence on a full half century of medical students, residents, colleagues, refering physicians, and most important of all, patients," Barbour adds.

CITY COUNCIL APPROVES STANFORD HOSPITAL MODERNIZATION

STANFORD—

The Palo Alto City Council on Monday (May 21) gave Stanford University Hospital the land use and environmental clearances needed to proceed with its $110 million modernization project.

The council unanimously declared that the project would have no significant environmental impact. Also approved without opposition was a motion recommending that the city zoning administrator approve a use permit for the project.

Meanwhile, project director Elvia Garwood said after the meeting that the first construction work, remodeling of space in the existing hospital, is scheduled to begin in mid-June.

Terming the hospital "a national and worldwide resource," council member Mike Cobb expressed his "hope that Stanford's project will be a success."

The council settled several weeks of controversy by approving a request for a change in zoning and in the city comprehensive land use plan for two parcels currently used for parking and a heliport along Welch Road.

The action taken by the council followed recommendations by the city's planning staff.

"We can now continue to do prudent planning for both Stanford University Hospital and Children's Hospital at Stanford," Garwood said after the meeting.

Council members Emily Renzel and Ellen Fletcher cast the only votes against changing the zoning on the land from office research to public facilities.

Lawrence G. Crowley, vice president for medical affairs at Stanford, told the council that without the zoning and land use changes, "it would be extremely difficult for us to proceed with the design of the new children's hospital until we know what site is available."

The city planning commission on May 2 had refused to follow a city staff recommendation and grant the zoning and a related city comprehensive land use plan change, saying it wanted more time to review the request and more information on the plans for children's hospital and the future uses of the existing children's hospital across Willow Road.

May 22, 1984 -more-

Plans are underway to move the children's facility to a an as-yet undetermined site adjacent to SUH.

Among issues was that the city comprehensive plan earmarked the heliport site as multiple family residential, although the zoning has remained office research. In past meetings, members of the plannning commission had said they were reluctant to give up the housing designation without an alternate site being selected.

In a letter to Mayor Lawrence A. Klein and the City Council, physician and former city council member William H. Clark said he felt it "would be irresponsible to place housing so close to a very busy tertiary care medical facility." Several council members referred to the Clark letter during Monday night's hearing.

In its action Monday night, the council declared that the project is consistent with the city's comprehensive plan, as long as specified parking utility, drainage, street right-of-way and related matters are met.

The next official approval, a use permit hearing before the city zoning administrator, was scheduled for 3 p.m. Thursday. Garwood said Monday's clarification of land use and zoning by the council should ease that and future discussions on land use or building design.

The modernization project is intended to provide remodeling needed to increase efficiency and comfort for patients. Uncompleted space in the existing hospital will be finished, and a four-story building with 190 new patient rooms will replace present inadequate and outmoded facilities. Adult intensive care will be consolidated and private rooms will be increased from 11 percent to 33 percent of the 663 licensed beds.

A 20-room surgery suite will be completed, intended to bring the operating room up to high technological standards and relieve delays and much off-hour scheduling for patients and physicians.

A total of 350,000 gross square feet of new construction is planned, and many of the facilities at the aging Hoover Pavilion annex—along with all pediatric facilities—will be consolidated at the Pasteur Road site.

Garwood said the first remodeling, scheduled next month, will be of the cardiovascular angiography area. Current plans call for excavation and new construction to begin in September.

FACULTY GROUP FINDS COMMON GROUND FOR MEDICINE, HUMANITIES

STANFORD—

A group of Stanford University faculty members from the medical school and other departments have joined to explore areas of common interest and develop future interdisciplinary course offerings.

The Committee on Medicine and the Humanities was formed under the auspices of the associate dean of humanities and sciences for undergraduate programs, Carolyn Lougee, and the dean of the school of medicine, Dr. Dominick Purpura, in hopes of establishing formal academic programs oriented toward the interaction of medicine with history, philosophy, ethics, economics, and social sciences.

"We find at the medical school that there's a great deal of emphasis on research and new technologies, and not enough on the more human aspects of medicine," said Dr. Carlos Camargo, associate professor of medicine.

In some cases, similar courses are being taught at the medical school and main campus.

For example, Camargo and Dr. Bruce Parker, professor of radiology and chairman of the Committee, have taught a class for about 10 years on the history of medicine. "Meanwhile, several nonmedical faculty members have been teaching courses with similar and overlapping content in their departments," Camargo said.

These various courses "may not be known to interested students because they are sponsored by so many different departments and schools."

Thus, the Committee is in the process of compiling and collating existing courses in which interactions between medicine and the humanities play a prominent role.

Another activity the Committee plans is to provide advisors, and possibly research opportunities, for interested undergraduates and medical students, in the schools of engineering, business, and law, as well as the school of medicine and the school of humanities and sciences, Parker said.

"Our hope is that we can generate sufficient interest among the faculty that a series of faculty seminars can be planned for the 1984-85 academic year."

5-21-84

-more-

"We believe that these proposed activities would prove advantageous in the recruitment of highly qualified prospective medical students," the Committee, formed about six months ago, stated. "There is an erroneous perception of the (medical) school, that all too often influences some of our most desirable applicants, that we emphasize basic research at the expense of concern for the more humanistic and humanitarian aspects of medicine."

Purpura noted that "the Committee on Medicine and the Humanities provides a forum for reemphasizing the role of ethical, moral, philosophical, and artistic attributes of human interactions in the universe of medicine."

The Committee already has sponsored two faculty colloquia dealing with the general theme of human values in medicine.

The first, held April 18, featured Dr. Albert Jonsen, professor of medical ethics at the University of California, San Francisco. The May 16 speaker was Michael Moore, professor of law at the University of Southern California, who discussed differing views of persons in law and psychiatry.

Present Committee members include Parker, Camargo, Dr. Raymond Clayton, professor of biochemistry and director of medical school admissions, Dr. Wilbur Knorr, associate professor of the history of science, Dr. David Stevenson, assistant professor of pediatrics, Dr. Peter Galison, assistant professor of the history of science, and Dr. Arnold Davidson, assistant professor of philosophy.

ALCOHOLISM AFFECTED BY WOMEN'S NEW ROLES, PSYCHOLOGIST SAYS

STANFORD—

A Stanford psychologist says alcoholism is becoming equal-opportunity in America.

"In the past, choices were a lot easier for women than they are today," said Cynthia Soyster, a psychologist at the Stanford Alcohol Clinic, speaking Thursday (May 17) at the second of four public lectures at Stanford University Medical Center. "There were very clear limits set on how much, where, with whom and when women could drink. Now women are winning the right to compete with men in every area of life, including the neighborhood bar.

"Alcohol promises to calm the conflict and anxiety of a woman's struggle for her rights."

Alcoholism in women is on the rise or coming out of the closet or both, Soyster said. "All the evidence we have points in that direction."

Soyster, a clinician who regularly treats alcoholic patients, said female membership in Alcoholics Anonymous (AA) has risen from 22 to 39 percent in a single decade. The number of women who use any alcohol increased 21 percent between 1939 and 1978, three times the 7 percent increase for men.

But it is very difficult to estimate the number of women with alcohol-related problems or who are alcoholic, for several reasons, she said.

First, the long-standing stigma of female drunkenness has evolved a conspiracy of silence. The problem drinker tends to hide her drinking, and family members assist her by "weaving a protective circle of silence around her to protect both her and themselves from the shame," Soyster said.

"Women collude in this denial," Soyster said. One study, she said, found that 86 percent of a group of alcoholic women seeking their physician's help failed to mention their alcohol problem, instead complaining of other physical or emotional problems. Misdiagnosing alcoholism as "nerves" or depression, doctors often prescribe tranquilizers that result in a second addiction, she said.

Although alcoholic men often are arrested for public drunkenness or driving while intoxicated, women are underrepresented in arrest statistics, Soyster said.

"The police are much more apt to scold her, give her a lecture, and send her home in a cab," she said.

May 21, 1984

-more-

In addition, questionnaires eliciting information on alcohol consumption are biased to exclude women. They ask such questions as "Have you ever had financial trouble (or had touble with the boss or the law) as a result of alcohol use?" Alcoholic men are much more likely to answer "yes," Soyster said.

Women alcoholics very often have their financial problems straightened out by men, are less likely to be employed, and seldom run afoul of the law, she said.

Soyster said one study found no difference in drinking patterns of single and married women under the age of 35. However, divorced or separated women under that age have the highest rate of problem drinking of any group of women.

"The legal and financial impact of divorce may be easier now than 15 years ago," Soyster said, "but there isn't much change in how much emotional pain goes along with all that."

Although a single event—like a change in an important relationship—often precipitates a woman's drinking problem, the event can be a positive one, she said.

"Stress and the use of alcohol to relieve that stress very often occur in people that have too much too fast, as well as when they have something wrong." she said.

While the benefits of light or moderate drinking for either sex are debated, researchers are uncovering physical differences between men and women in the way their bodies deal with alcohol.

Women become more intoxicated than men on the same amount of alcohol adjusted for body weight, Soyster said, and metabolize it faster.

She said this effect is exaggerated in a premenstrual woman. Oral contraceptives slow alcohol metabolism, Soyster said. "So women who use them stay drunk longer."

In addition, women are more vulnerable to cirrhosis or other liver problems after drinking less alcohol for a shorter time, she said.

Evidence is mounting that fetal alcohol syndrome is one of the leading causes of birth defects, Soyster said, and the risk of first-trimester spontaneous abortion is increased by drinking even moderately during pregnancy.

"It's important that women evaluate the potential risk they take during pregnancy in using alcohol at all," she concluded.

PATIENT OWES LIFE, AND NOSE, TO RECONSTRUCTIVE SURGERY

STANFORD—

This is the story of a man who lost his nose—and consequently his sense of self—to cancer, and recovered both thanks to the special techniques of reconstructive surgery.

Ethiopian Haile Habte-Miriam is finally ready to go back home after his three year ordeal. His quest for a nose that worked, and looked presentable, brought him from his native country to Kenya and finally to United States. He found what he was looking for at Stanford University Medical Center.

The young bank manager first left his wife and seven children when, nearly three years ago, his local clinic diagnosed a fast-growing lump on his nose as cancerous. He went to a hospital in Kenya, the closest institution that had radiation facilities. The radiation was effective in eradicating the cancer. Unfortunately, it also eradicated his nose.

The Kenyan physicians then proceeded, through a series of surgeries, to reconstruct his nose. "What the doctors did was just awful," said Haile's sister Addis, a nurse who lives in Berkeley. "They took a big flap of skin from Haile's forehead to rebuild his nose, but didn't put in any cartilage to form it. They didn't create any nostrils. The nose was very deformed. It was frightening."

The physicians then replaced the skin from Haile's forehead with skin from his thigh, which was a completely different color and texture. When it was time for him to go back to Ethiopia, he didn't even call his family to say he was coming home.

"I was so depressed ," Haile recalled. "When I walked in my house my children didn't recognize me. When I walked down the street no one recognized me either because of my nose."

Addis was devastated to learn of Haile's fate. "I knew Stanford was the best hospital," she said. "The first thing that came into my mind was 'I have to call Stanford to see what can be done.' "

Days later, ear, nose, and throat specialist Dr. Richard Goode examined the medical records and photographs of Haile that Addis had brought. He finally looked up at Addis. "Your brother's nose is a challenge," Addis recalled him saying. "I can help him. Tell him he should come to Stanford."

5-21-84 -more-

Haile arrived shortly thereafter, having obtained permission to come to the U.S. from the Ethiopian government, taken a leave of absence from his job, and sold his house and other personal belongings to help finance his treatment. The planning of Haile's new nose began.

"Noses are difficult to work on because they're so obvious, and they change as they heal," Goode explained. "They usually change for the worse. That's why there are so few physicians who work on them, and even fewer that do them well.

"I'm sure there are quite a few people, like Haile, with noses that don't work or look good that have been told there's nothing that can be done," he added. "But that's not necessarily true."

In the first of four surgeries, Goode inserted cartilage to shape Haile's nose. At the same time, he inserted something called a Radovan expander under the skin on his forehead.

The expander, originally developed by a southern California physician to use in breast implants, is a small silicone bag. Injecting it with saline solution causes it, and the skin covering it, to slowly stretch much like a pregnant woman's belly. In addition to building up the nose during ensuing surgeries—folding cheek skin over to form nostrils, revising some of the scars, and more—Goode was able to pull the stretched skin almost completely across Haile's forehead. Thus, he was able to get rid of the grafted skin from Haile's thigh.

"Dr. Goode is amazing," Addis exclaimed. "When he showed us by folding his tie how he was going to fold Haile's cheek skin to make the nose, we didn't believe him. But it worked!"

"Haile's appearance is much improved," Goode said. "He can breathe through his nose, which he couldn't do before, and he's happy with the way he looks."

Haile has one more touch-up procedure to undergo, and then it's back home to Ethiopia to resume his life that was so suddenly interrupted. He's worried about paying his bills— which came to about $20,000—in addition to reestablishing his family's lifestyle. Regardless of any hardships he may confront, Haile said the experience was well worth it.

"Dr. Goode created me," he said. "Because of him, I'm a new man."

SCIENTISTS MEASURE HOW CELLS IN THE EYE

RESPOND TO LIGHT'S RAINBOW OF COLORS

STANFORD—

Stanford University scientists have successfully measured how single cells from the retina of the eye respond to light of different wavelengths, with a technique much more sensitive than any used before.

The research marks the first time that direct electrical recordings have been obtained from the color vision cells of primates' eyes.

"The measurements provide new and basic information needed for understanding color vision," said Dr. Denis Baylor, professor of neurobiology at Stanford University School of Medicine.

The report was published in the May 17 issue of the British journal *Nature* by Baylor and two postdoctoral colleagues, Dr. Brian Nunn, now at Cambridge University, and Dr. Julie Schnapf. The research was supported by grants from the National Eye Institute.

Color vision begins when light is absorbed by pigments in "cones," specialized light-detecting cells about six million of which are found in each eye. The cones are highly packed at the retina's center and dotted more sparsely around its periphery.

Three "flavors" of cone cells contain pigment molecules that preferentially absorb light in the red, green and blue regions of the color spectrum.

When a cone absorbs light it generates electrical signals which are transmitted over a chain of nerve cells to the brain.

"It is well known that hue is determined by how strongly light excites the red-, green-, and blue-sensitive cones," Baylor said.

What has not been known with much precision, he added, is the exact sensitivity of each type of cone to wavelengths of light through the visible spectrum.

To find this out, Baylor and his colleagues used an extremely precise method for determining exactly how strongly various wavelengths of light excite each type of cone cell.

The research provides a beginning toward understanding how the visual system encodes color information, Baylor said. Next, scientists will have to figure out how the central nervous system detects the strength of electrical signals from each of the three types of cones, Baylor added, a task that involves sorting out the neural wiring connecting eye and brain.

In commentary accompanying the report, Dr. John Mollon of Cambridge University noted that the "pioneering" research provides "the first direct electrical recordings from primate cones." The work makes it "technically possible" to find solutions to a host of unanswered questions about how color vision works, he added.

The Stanford researchers measured electrical signals generated by single red- and green- sensitive cones from the retinas of macaque monkeys, thought to have cone pigments and color vision very similar to those of humans. They plan to perform similar work on blue cones and also on cells from human retinas, Baylor said.

They used a special technique developed by Baylor's laboratory in 1977 for examining retinal cells one at a time. The technique is more sensitive than previous methods because it measures the amplified electrical signals that the cell generates when it absorbs light rather than simply measuring whether or not light is absorbed by the cell.

The method employs a tiny glass tube into which a portion of a single cell can be drawn with mild suction. The tube's outside diameter is about one-third the thickness of a human hair. The inside of the tube is hooked up to amplifying equipment for measuring electrical current from the cell.

After drawing a single cell into the tube, the researchers shone light of different wavelengths on it. Using this method, they were able to measure sensitivity to all the wavelengths in the visible part of the spectrum, Baylor explained.

"This kind of measurement gives the probability that each type of pigment molecule will absorb light of any particular wavelength," he said.

In addition to providing a step toward understanding color vision, the research Baylor and his colleagues are doing is also aimed at explaining how light is converted into an electrical signal inside cone cells.

COMPUTERS MEASURE CORONARY ARTERY BLOCKAGE MORE PRECISELY THAN EVER BEFORE

STANFORD—

Stanford University Medical Center researchers are using computers that measure blocked coronary arteries in heart patients more precisely than ever before in a study funded by a $1.5 million grant from the National Heart, Lung and Blood Institute.

The study, which began Jan. 1, 1984, will determine whether modifying known risk factors for coronary artery disease affects the rate at which the arteries become blocked.

The new computerized technique gives physicians a better tool with which to determine just what percentage of the arteries are functioning without having to rely on subjective judgments or interpretations, said Dr. Edwin Alderman, associate professor of medicine.

The study, called the Stanford Coronary Risk Intervention Project (SCRIP) will involve as many as 300 patients with coronary artery disease at Stanford, the Palo Alto Veterans Administration Medical Center, and Sequoia Hospital during the next three years, Alderman said.

Patients in the study are randomly assigned to two groups. Members of one group get aggressive treatment to lower known risk factors, including cigarette smoking, physical activity, stress, blood pressure levels and diet. Members of the second group follow the regular care of their physicians. By using computers to compare patients' X-ray pictures of their coronary arteries, scientists will measure the exact percentage of change that occurs over the three years.

"Determining the rate of narrowing in the artery has always been subjective," Alderman said. "One person may say there's a 50 percent narrowing, while another person may say there's a 70 percent narrowing."

With the generally accepted conclusion that an artery blockage of 70 percent or more necessitates surgery, a more precise measurement may be important to a patient, Alderman said. But where it's essential, he added, is in research on the effectiveness of therapies for coronary artery disease, and more.

The new technique, developed by Alderman, William Sanders, a cardiology research associate specializing in computers, and Dr. Donald Harrison, cardiology chief, takes the standard angiogram, or X-ray picture of the heart, and converts it to digital units via a specialized projector. This enables a computer to analyze it. The computer operator can instruct the computer to outline the walls of the arteries in question, and then by analyzing the various hues of black, grey, and white that the artery is projected in, to compute the percentage of blockage for any designated segment.

The technique is "highly reproducable" Alderman said, thus enabling physicians to analyze the same artery segment at different times to compare, or simply to double check their findings.

"The general idea is to try and reduce the variability that is involved in physician interpretation of angiograms," Alderman said.

REAGAN APPOINTS STANFORD PATHOLOGY DEPT. CHAIRMAN TO NATIONAL CANCER ADVISORY BOARD

STANFORD—

Dr. David Korn, professor and chairman of the department of pathology at Stanford University School of Medicine has been appointed a member of the National Cancer Advisory Board (NCAB), the White House announced Tuesday May 15.

Korn, 51, is one of five new members appointed by President Ronald Reagan to six-year terms on the NCAB, effective May 17, 1984 and expiring March 9, 1990. The five new appointees succeed NCAB members whose terms expired last March, according to an official at the National Cancer Institute (NCI).

The National Cancer Advisory Board, created by the National Cancer Act in 1971, is a 29-member group that advises and assists the NCI director with respect to activities of the National Cancer Program, the United States' comprehensive effort aimed at combatting cancer. One of its major responsibilities is the approval of research grants awarded by the NCI, which in 1983 amounted to nearly $600 million.

Eighteen of the NCAB's members are scientists, physicians, and members of the general public appointed by the President. The scientists and physicians appointed to the NCAB are among "leading scientists or medical authorities outstanding in the study, diagnosis, or treatment of cancer, or related fields," the NCI said.

The NCAB also has 11 non-voting *ex officio* members from a variety of governmental agencies, including the Secretary of Health and Human Services, the director of the National Institutes of Health, the Food and Drug Administration commissioner, and the administrator of the Environmental Protection Agency.

The NCAB meets at the behest of the director of the National Cancer Institute at least four times each year.

Korn, who received both his undergraduate and medical degrees from Harvard University, has been on the Stanford Medical School faculty since 1968.

His research focuses on enzymes involved in controlling DNA replication inside cells of higher organisms. These enzymes, called DNA polymerases, are thought to play an important role in regulating cell division, a process that goes awry when cells become cancerous.

He has written numerous articles and is a member of the editorial boards of the *American Journal of Pathology* and *Human Pathology*. He is also a member of the board of directors of the California Society of Pathologists and serves on several other professional boards and councils.

Korn has also previously served as an advisor on cancer to the federal government. He was a member of the Board of Scientific Counselors, Division of Cancer Biology and Diagnosis, National Cancer Institute, from 1977 to 1982, serving as chairman from 1980 to 1982.

STANFORD OPERATES RADIATION THERAPY PROGRAM IN FREMONT

STANFORD—

Stanford radiologists are expected to begin treating East Bay cancer patients starting July 1 at an outpatient facility in Fremont owned by Washington Hospital.

Dr. C. Norman Coleman, associate professor of radiology, said Dr. Francine Halberg, who is joining the Stanford faculty in July, will be assigned fulltime to the new facility "which will enable patients in the Fremont area to find the outstanding care and expertise they have been accustomed to at Stanford in a community facility nearer home." Stanford is about 20 miles or a 25 minute drive from the new facility.

In addition to at least one fulltime faculty member assigned to the center, other physicians in Stanford's Department of Radiology would be available on a consulting basis, along with residents assigned to the Stanford program, he said. About 150 to 200 patients annually are expected to be treated in Fremont, Coleman added.

The new 3,600-square-foot cancer radiation facility has a linear accelerator and other state-of-the-art equipment housed in a lead lined building across the street from Washington Hospital, which until now had no radiation therapy services, Coleman explained. Professional physician services will be under the auspices of the Faculty Practice Program, the clinical practice arm of Stanford's medical faculty.

Donald Tower, FPP executive director, said this is the only current satellite program of the FPP.

"Many of these Fremont-area cancer patients had to drive or be driven to Stanford for regular therapy treatments," Coleman explained. "We are extremely pleased that we will be able to continue to offer them the same level of service at a location which they can reach more quickly and more conveniently," Coleman added.

"This is a joint venture and partnership, and we are very pleased to be able to move the physicians and the talent of Stanford instead of moving the patients" across the bay, said Dick Warren, administrator of Washington.

Coleman said the project evolved following discussions with community physicians in the Fremont area. For several years, Coleman said, he had been holding monthly sessions to discuss cancer cases with East Bay physicians. The monthly meetings were organized in Fremont by Dr. David Cheng, a local oncologist.

"We hope to be a valuable resource to the physicians in the community," Coleman added.

The new center was built by a private businessman who sold it to the hospital for a price of between $1.5 and $2 million, said Warren.

Radiation therapy is one of the most common forms of treatment for many types of cancer. It is often administered in conjunction with drug therapy and requires daily visits for five to six weeks, Coleman said.

HEALTH FAIR HELPER PARLAYS HEART ATTACK TO NEW ART CAREER

(Editors: Photos of Chesnut and artwork available on request)

STANFORD—

Merritt E. (Gene) Chesnut was "the kind of guy who never goes to see a doctor" when he became ill during a camping trip in 1973.

Now the Palo Alto artist is an amateur expert on America's number-one killer—cardiovascular disease.

"For a layman, I know about as much about the heart as there is to know," he said, laughing.

Chesnut has designed the poster logo—a cartoon jogger—for the second annual Heart Health Fair, scheduled Saturday, May 19 at the Stanford Shopping Center from 10 a.m. to 4 p.m. Sponsored by Stanford University Hospital's nursing service, the fair offers visitors information on the prevention, diagnosis, and treatment of heart disease.

"The more information people have, the better they can take care of their own bodies," said Joan Caldwell, chairperson of the adult cardiac patient education committee. "People can make changes in their lives to prevent heart disease and can recognize the early symptoms."

Now 65, Chesnut discovered that his camping-trip illness was a heart attack only after he was hospitalized that night at Stanford. The next day, he underwent double coronary-bypass surgery, and his education in heart disease began.

After another heart attack in 1981, Chesnut again was hospitalized at Stanford. This time he had his art supplies and soon felt well enough to sketch the scene around him. His hospital-life cartoons rapidly won fans.

Now the retired U.S. Marine Corps officer and bank executive has a new career. The heart-fair logo is the latest of many illustrations he has done—free of charge—for Stanford nursing service publications. Most are for booklets that explain diseases and hospital procedures to patients.

"It's something to do, and I get a lot of pleasure out of it," he said.

Chesnut and other visitors at the Heart Health Fair will find nineteen booths located around the mall. Some highlights include:

- For $10, visitors can have blood drawn for a panel of tests--like blood cholesterol and triglyceride (fat) levels--that will help them assess their risk of developing heart disease. These tests usually cost about $40. If possible, participants should eat nothing for four hours before their blood is drawn.
- Free blood pressure checks will be available at many booths.
- Visitors can get a free EKG tracing of their heart rhythm.
- Operating room nurses from Stanford will display pacemakers, artificial heart valves, surgical instruments used in heart operations, and photos of heart surgery.
- Visitors can learn how heart-lung transplants are done and how donor organs are obtained.
- Palo Alto Fire Department paramedics, trained by Stanford Hospital, will have their ambulance open for display and will demonstrate some of their equipment.

CHILDREN OF ALCOHOLICS FACE BURDENS IN ADULTHOOD

STANFORD—

Unresolved feelings of abandonment and insecurity comprise the emotional baggage many children of alcoholics carry with them into adulthood, said Dr. Susan Beletsis, clinical psychologist at the Stanford Alcohol Clinic, speaking at the first of four public lectures Thursday evening (May 10) at Stanford University Medical Center.

"There were two rules these people grew up with," Beletsis said. "One was, 'There's nothing wrong here,' and the other was, 'Don't tell anyone.' " Under these conditions, it becomes very easy for a child to feel somehow responsible or guilty, and to want to fix the family's problems.

"A simple command like, 'Don't spill your milk, you'll upset your father' takes on an added dimension in an alcoholic household. It means you have the power to make your father drink or not," Beletsis said. "Even when these people later realize it's not true, it never quite erases that early belief."

That's why many of these adults, who may have lived away from their parents for years, still feel their purpose in life is to solve their original family's problems, and many return home, even leaving a new marriage, "just to try one more time."

In an emotional sense maybe they do need to go home, Beletsis suggested, in the sense of allowing themselves to come to grips with childhood feelings.

A beneficial way to do this, she noted, is through group therapy with others who've been there. More than 200 adult children of alcoholics, mostly women, are seen at the Stanford Alcohol Clinic every year, Beletsis said, mainly in small groups but sometimes individually.

Participating in a group may bring a sense of betraying the family, Beletsis said, which is why many don't tell their families they're doing it at first.

But soon the group becomes a sort of replacement family.

Common problems members discuss are high self-expectations, pervasive feelings of failure, depression, and difficulties in interpersonal relationships, Beletsis said. Conscious wishes are in conflict with deep-seated emotions.

Lack of a healthy role model in the family can make self-identity difficult. Ironically, the alcoholic parent may be more loving, while the other parent is often depressed and angry. The child wants to be a non-alcoholic, but still identifies strongly with the alcoholic parent.

Separation from the family has also been traumatic, Beletsis said. Many children end up abusing alcohol or drugs themselves.

As adults they've often chosen, as their life partner, another very dependent—even alcoholic—person to be with. It's hard for them to relax at all; if someone is five minutes late it can be a source of great anxiety.

Many therapy groups last for two to three years, Beletsis said, and people leave at different times. Therapists ask for long-term commitments, since they feel the groups should be stable.

The issue of separation from the group almost always brings forth some feelings of abandonment, Beletsis noted.

"But in general people ready to leave have experienced changes in their interpersonal relationships. Often they'll go back to visit their parents with a new perspective," Beletsis said.

"The going home—whether real or symbolic—represents an acceptance and recognition in a person's own mind—'This did happen, but I'm not responsible.' The memories probably don't change, but the meanings attached to them do," she concluded.

The next talk in the series, "Women and Alcohol," will be presented 7:30 p.m., May 17, in room M104 of the medical school. The speaker is Dr. Cynthia Soyster, psychologist at the Stanford Alcohol Clinic. For further information call Diana Kennedy at (415) 497-6682.

SCIENTISTS STUDY ACTION OF DIOXIN

AT THE MOLECULAR LEVEL IN MAMMALIAN CELLS

STANFORD—

Dioxin—a chemical contaminant of herbicide manufacturing—can act to "turn up the volume" of certain genes in the DNA of mammalian cells, Stanford University researchers have found.

Dioxin's ability to modulate the way in which cells express their genetic material could help explain some of its toxic effects in animals as well as provide a clue about the substance's alleged harmful effects in humans.

It also provides researchers with a powerful tool for studying how cells regulate expression of their genes, the pieces of hereditary material that encode all the instructions for cells to properly function, said Dr. James Whitlock, associate professor of pharmacology at Stanford University School of Medicine.

Whitlock and graduate student David Israel are studying TCDD, the most powerful member of the dioxin family of chemicals that achieved notoriety as contaminants of the Vietnam war defoliant Agent Orange.

The problem of sorting out dioxin's effects on health is not a simple one, Whitlock noted, because the substance displays different levels of activity in different animals. For example, it takes 5,000 times as much of the chemical to kill guinea pigs as to kill hamsters.

In humans, the effects of dioxin exposure have not been rigorously studied, Whitlock said. Its only established medical hazard is production of chloracne, an acne-like proliferation of skin cells, he added.

One way to study dioxin's health effects is to look at how the chemical acts on DNA at the molecular level. "We are finding that at the molecular level, dioxin plays a complex role," Whitlock said.

In an article published in the May 10 issue of the *Journal of Biological Chemistry*, the scientists report that dioxin induces mouse cells to "read out" the information contained in a specific gene at up to 20 times the normal rate.

The gene codes for an enzyme that helps rid mammalian cells of potentially harmful compounds. Called cytochrome P-450, the enzyme initiates chemical processing of potentially harmful substances that might otherwise accumulate to toxic levels inside cells.

5-10-84

-more-

In the detoxification process, the toxic chemicals go through transient "activated" stages, when they are highly reactive. If these transient molecules come in contact with DNA, their reactivity can be deleterious, Whitlock stated. But it is too early to speculate on what this might mean in terms of human effects, Whitlock cautioned.

Genetic strains of mice that are more resistant to dioxin have been developed by other researchers, Whitlock said. There could be genetic differences among humans too, he added, causing certain individuals to be more susceptible to dioxin. "But we do not yet know enough to say whether this is true, or to identify individuals with higher or lower susceptibility," Whitlock said.

Again, molecular level studies should help toward this goal by explaining how dioxin acts to alter expression of the genetic material, Whitlock said.

Dioxin seems to act on DNA in a two-step process, the researchers reported. First the dioxin molecule binds—perhaps in matched lock and key fashion—to a receptor protein inside the cell. Next, the dioxin-receptor complex accumulates within the cell nucleus where it attaches to the DNA.

Attachment of the dioxin complex to a specific site on the DNA causes the cell's machinery to transcribe, or "read," the cytochrome P-450 gene more frequently than before, ultimately causing the cell to produce greater quantities of the cytochrome P-450 enzyme, Whitlock said.

This mode of action of dioxin has given Whitlock and Israel a biochemical explanation for mice that are more resistant to dioxin. In these mice, the dioxin receptor protein is abnormal. Unable to bind with the defective receptor molecule, dioxin cannot attach to the DNA to boost expression of the cytochrome P-450 gene.

The dioxin research may also lead to more general insights about how cells regulate their genes, Whitlock said.

Many genes are thought to be controlled by "inducer" molecules that boost their expression, Whitlock said. But the chemical identity of only a few inducers has been discovered, he said.

"In this case we have identified dioxin as one of the inducer molecules that increases expression of a gene, giving us a powerful system for studying gene regulation," he said.

The research is supported by grants from the National Institutes of Health, the American Cancer Society and the Pharmaceutical Manufacturers Association Foundation.

ASSOCIATE DEAN GIVES MONEY FOR KIDNEY STUDIES

STANFORD—

A $50,000 gift to help Stanford University Medical Center students pursue research projects related to the kidney and its disorders has been provided by Satellite Dialysis Centers Inc., of Menlo Park (Calif.).

The gift, announced Friday (May 6), honors Robert L. Maffly, son of Roy H. and Marilyn Maffly, who died suddenly last year at age 28. A graduate of Whitman College and recipient of an M.S. in chemistry from the University of California at San Diego, the younger Maffly was employed at SRI International as an industrial economist.

His father is professor of medicine (nephrology) and associate dean for student affairs at Stanford Medical School.

The Robert L. Maffly Fund grew from Satellite's interest in kidney research and Dr. Maffly's conviction that "research experience is an essential part of medical education."

Dr. Norman S. Coplon, president of Satellite was a clinical and research fellow under Maffly in the Division of Nephrology from 1967 to 1969. When he completed his fellowship, Coplon helped establish Stanford's kidney dialysis unit, becoming its first director.

When Coplon left Stanford in 1974 to establish Satellite Dialysis Centers, a group of nonprofit freestanding dialysis facilities in San Jose, Modesto and Palo Alto, Maffly became a member of the corporation's board of directors, on which he still serves.

The fund, which will remain open to future donations, will be administered through the Stanford Medical Alumni Scholars' Fund, which provides research stipends and tuition credits for Stanford medical students.

MASS MEDIA PROVIDE NEGATIVE IMAGE OF NURSING, TWO RESEARCHERS SAY

STANFORD—

The professional image of nurses has reached an all-time low in the popular entertainment media, two University of Michigan professors told an audience of Stanford University Hospital (SUH) nurses Wed., May 9.

Despite the fact that today's nurses have greater health care responsibilities than ever before, they are being portrayed as less intelligent, less nurturing, and less empathetic in novels, film, and television than at any time in the last 80 years, said Drs. Beatrice and Philip Kalisch, both professors of nursing at the University of Michigan.

Since the mid-1960s, the dominant stereotype of the nurse in the mass media has been as a sex object, the professors said.

This negative image of nursing, if left uncorrected, will lead to problems in nurse recruitment, funding, and the future role of nurses in the health care field, the Kalisches predicted.

"A public constantly fed a demeaning image of nursing will not perceive the profession as a desirable or prestigious one," Philip Kalisch pointed out.

The Kalisches were the featured speakers during Stanford Hospital's nursing department's first annual "Stanford Nursing Week."

The husband-and-wife team is conducting a study of how the nursing profession is portrayed in the mass media.

Although the public sees nurses as "nice people," the nursing profession is given little prestige in the public eye, the Kalisches said.

In the future, nurses should attempt to foster an image of themselves as dedicated "careerists" and encourage the nursing profession to be recognized as a vital industry offering discrete services, the professors added.

In their research, the Kalisches looked at news and entertainment depictions of nurses in the mass media. To evaluate news coverage, they said they examined 10,000 newspaper articles, 5,000 photographs, 350 television newscasts, and 15 magazine articles. In the entertainment media, they looked at the image of nurses as conveyed through 216 novels, 212 films, and 351 television episodes.

5-9-84 -more-

Overall, during the past 80 years there has been a decline in positive portrayals of nurses, the researchers said, with brief interludes of more favorable coverage of the profession during the two world wars.

Newspaper coverage of nursing presents the most positive, realistic image of the nursing profession, the Kalisches said, but the quantity of coverage is small and thus not very influential in shaping the public's view of the nurse.

Television presents the least favorable coverage, depicting nurses as harming patients twice as often as it shows them helping patients, the Kalisches reported.

Novels—except those written by physicians—frequently present a positive image of nursing, but since television is "the most exposed of the media, the negative nurse image is more strongly reinforced in the public mind," the researchers said.

One of the major dangers of a negative public image is that it will adversely affect the number and quality of people who choose nursing as a profession, the Kalisches said.

This is a particular problem in terms of recruiting men into the profession, the Kalisches said. As women—who have traditionally comprised over 95 percent of the profession—begin to migrate into other fields, men have no role models that would entice them to consider a nursing career.

"We need a new TV series called "Joe Smith, R.N." starring Tom Selleck, a macho but sensitive man who chooses to become a nurse" Philip Kalisch suggested. "Such a positive presentation would induce 50,000 male adolescents to think about nursing as a career."

The Kalisches concluded by telling the audience that nurses must reshape the negative public image of their profession by more active participation in conveying what it is that nurses really do.

"Write letters to local newspapers, write novels about nurses, develop good relationships with local reporters, establish the nurse's role as an authority in certain aspects of health care," Philip Kalisch suggested. "You may get misquoted occasionally, but invisibility in the media is the highest price any group can pay."

In addition to the lecture by the Kalisches, Stanford Nurse Week, May 6-12, features exhibits and tours of nursing activities at Stanford University Hospital's main center and Hoover Pavilion.

MICROBIOLOGIST RECEIVES FELLOWSHIP AWARD IN MOLECULAR PARASITOLOGY

STANFORD—

Dr. John Boothroyd, assistant professor of medical microbiology at Stanford University School of Medicine, has been granted a special fellowship award in molecular parasitology from the Burroughs Wellcome Fund of North Carolina.

The $40,000 two-year fellowship was recommended by the advisory committee of the Burroughs Wellcome Fund in special recognition of Boothroyd's research accomplishments and potential, said Martha Peck, the Fund's executive director.

Boothroyd, 29, studies the molecular biology of *Trypanosoma brucei*, the single-celled parasite that causes African sleeping sickness.

This organism, which accounts for thousands of deaths annually on the African continent, has an unusual ability to elude the protective forces of its host's immune system. Like a criminal with a repertoire of "aliases" the parasite repeatedly switches the make-up of its protein coat, assuming a new disguise to stay one step ahead of the host's immune response.

Learning more about the genetic basis for this ability could have broad implications for understanding infectious disease at the molecular level, said Dr. Stanley Falkow, chairman of medical microbiology at Stanford.

Boothroyd, who joined the Stanford faculty in 1982, did his undergraduate studies at McGill University in Canada and received his Ph.D. in molecular biology from Edinburgh University in Scotland in 1979.

The Burroughs Wellcome Fund, based in the Research Triangle Park area of North Carolina, has a longstanding interest in funding research related to tropical medicine.

GONDA RECEIVES ACHIEVEMENT AWARD FROM PSYCHIATRIC SOCIETY

STANFORD—

Dr. Thomas A. Gonda, professor and chairman of the department of psychiatry and behavioral sciences at Stanford, is co-recipient of the 1984 Outstanding Achievement Award of the Northern California Psychiatric Society (NCPS).

The award, presented April 28, honors NCPS members who have made outstanding contributions to psychiatry and earned the respect of their colleagues and the community.

Gonda was honored for his "multitudinous achievements," said Dr. Lorrin Koran, co-chairman of the awards committee. Gonda has written more than 50 professional papers and is co-author of a recent book, *Dying Dignified: The Health Professional's Guide to Care.*

The second award was presented posthumously to Dr. Victor Calef, who was a San Francisco psychoanalyst.

SCIENTISTS TELLS CONGRESS OF NEED FOR NEW FEDERAL HELP

STANFORD—

The government should take a wider role in the distribution of biotechnology, and the federal agency responsible for medical hardware advancement should be better funded, a Stanford scientist told a Congressional subcommittee Monday.

Dr. Oleg Jardetzky, professor of pharmacology and chairman of the directorate of the Stanford Nuclear Magnetic Resonance Center, said the federal Biotechnology Resources Program should have its role expanded to facilitate the distribution for public use of expensive biomedical innovations.

Jardetzky has said in the past that multimillion dollar equipment needed for medical research and treatment will need to be shared among several institutions, and its introduction to practical applications must come from public funding sources.

Speaking on behalf of a panel of 15 scientists, Jardetzky was scheduled to testify before a subcommittee—chaired by Rep. William H. Natcher, D-Ky.—of the House Committee on Appropriations.

"Over the past decade it has become increasingly clear that complex and sophisticated technology—high speed computers, high resolution Nuclear Magnetic Resonace (NMR) instruments, synchrotron radiation facilities, million electron volt electron microscopes and others—will have an enormous impact on the future course of medical science and clinical practice," Jardetzky said in remarks prepared for delivery to the Subcommittee on the Departments of Labor, Health and Human Services, Education and Related Agencies.

But he said the cost of new lifesaving biotechnology devices can range from $1.5 million to $2.5 million, with construction costs for facilities supporting the new equipment ranging up to about $10 million.

"The categorical institutes of the NIH (National Institutes for Health) have no instrumentation programs capable of handling proposals requiring a capital outlay of this order of magnitude," he said.

Jardetzky noted that the NIH's Division of Research Resources-The Biotechnology Resources Program has been funded inadequately for $32.5 million in fiscal 1984, with an increase only to $34.4 million next year. Funding should be increased at least $5 million next year that funding in the range of $64 million should be the goal in the next five years.

The scientist said the NIH could facilitate distribution of needed new technology by encouraging commercialization whenever possible, replicating prototype instruments, and funding or providing such equipment "where commercialization is not feasible for reasons of either very high costs or of a limited market."

He said the BRP should change its name to "Biotechnology Research and Resource Program" and should also become involved in interdisciplinary training programs where traditional degrees cannot meet quickly changing and innovative needs.

Jardetzky said the panel's recommendation "represent the minimum steps necessary to establish a program with the NIH that will adequately meet the needs of U.S. medical scientsts for a new sophisticated technology and provide an opportunity for U.S. leadership in the introduction of modern technology into medical research and clinical practice."

Other Stanford scientists on the panel who endorsed Jardetzky's testimony were Arthur I. Bienenstock, professor of materials science engineering and applied physics and director of the Stanford Synchrotron Radiation Lab; Edward A. Feigenbaum, professor of computer sciences; and Edward H. Shortliffe, assistant professor of medicine.

TRADEOFFS BETWEEN PROLONGING LIFE AND COSTS POINTED OUT IN STUDY

STANFORD—

Patients treated by faculty physicians in a university hospital had higher costs and lower inhospital mortality than patients with the same diagnoses treated in the same hospital by private practice physicians, according to a study reported Thursday by the National Bureau of Economic Research (NBER) and Stanford University School of Medicine.

The differences in cost and mortality between the two services were especially large for the most seriously ill patients. But although the inhospital death rate was twice as high for patients of private physicians, followup revealed that the survival rates were low and equal for the two services nine months after discharge.

The researchers studied records of 2,025 patients admitted in 1981 to Stanford University Hospital by the two categories of physicians. The researchers measured differences in types of cases, costs and mortality in the hospital as well as whether higher costs were associated with differences in short and long-term utcomes.

The latter is important, the researchers said, because if academic medical centers are to continue to provide the same level of care to patients they have admitted in the past, the proposed payment system must have adjustments to allow for the care of those high-risk patients.

Patients in the study were assigned to four risk categories based on their predicted probability of death. The study found that for low-risk patients the cost differences between faculty and community services as well as mortality in the hospital were small and statistically insignificant.

But the costs of caring for high-risk patients were 70 percent higher on the faculty service than on the community service, and they were due to aggressive treatment and diagnostic tests. The faculty patients had significantly fewer inhospital deaths.

More strikingly, a followup of a matched sample of patients from the high-risk category revealed that only 16 percent of the patients of either group survived nine months after discharge.

The study co-authored by Drs. Alan M. Garber, Victor R. Fuchs and James F. Silverman was published in the May 10 issue of *The New England Journal of Medicine*. Supported by a grant from The Robert Wood Johnson Foundation to NBER, the study was done to gain insight into the consequences of prospective payment for university hospitals which have higher costs because of the mix of high-risk patients they care for. Prospective payment based on diagnosis is perceived to threaten the financial stability of teaching hospitals.

This system of payment, to be phased in a four-year period, has been mandated by Congress to hold down Medicare costs. Hospitals are to be paid according to fee schedules determined in advance for 467 Diagnosis Related Groups (DRGs) of illnesses. The DRG system, some experts predict, would not be limited to Medicare payments, but eventually could determine the bills of all patients.

5-7-84

-more-

2-2-2 The differential in costs on the faculty service probably reflects in part the hospital's role as a training institution and referral center, according to the study. "House staff (interns and residents) and medical students who learn by doing procedures and interpreting diagnostic tests, may order studies more readily because of their educational value.

"Physician attitudes toward death may also have contributed to the more aggressive care on the faculty service. Private physicians, who knew their patients better, may have been more aware of the patients' own wishes concerning continued life support. In many cases, the patients' preferences may not have been known to the faculty physicians, who would have treated aggressively when in doubt."

According to the study, the more extensive use of diagnostic procedures and intensive care provided on the faculty service may have reduced mortality while generating higher costs. But because the patients of the two groups of doctors may have differed, the results do not prove that faculty physicians actually reduced mortality through more care.

"Community physicians may also have waited longer to admit their patients to the hospital than did the faculty," the researchers said. "By substituting outpatient for inpatient services, the community physicians may have increased the proportion of their patients who were in the final stages of illness, while reducing costs."

The study of only one university hospital, the researchers acknowledge, is not sufficient to make their observations applicable to all hospitals. But "the differences we observed between the faculty and community services in the same hospital are likely to understate the differences between separate teaching and community hospitals." At Stanford, they said, community and faculty physicians interact more closely than faculty and community physicians in separate hospitals.

In an accompanying editorial in the same issue of the journal, Editor Dr. Arnold S. Relman commented:

"This report from Stanford deserves careful consideration. It tells us that an important part of the added costs of teaching hospitals is probably due to the increased intensity of workup and treatment of very sick patients, and that this increased care appears to produce measurably greater inhospital survival.

"The message here seems to be that the relatively high costs of teaching hospitals will need to be weighed against the medical results achieved in such centers, as well as their educational and research outputs."

"The study," Fuchs stressed in an interview, "says there may very well be a tradeoff between prolonging life and costs, and that is something we as a society have to face.

"It shows also that patients and physicians have differences of opinion on how they deal with death and dying. Some physicians accept it as a fact of life, others want to do all they can to prevent it. Some patients also do cling to life and want to have everything possible done.

"But when the government sets the rules, it becomes a controversial issue. Institutions that continue to practice high cost medicine that is typical of the faculty service will incur financial penalties. Less aggressive services will become more common, and we may see hospital mortality rise.

"An important consequence of prospective payment will be overlooked if government policy makers do not monitor hospital mortality."

MOLECULAR AND GENETIC BASIS OF DISEASE DISCUSSED AT STANFORD SYMPOSIUM

STANFORD—

Gene transfer into mammals is still a crude procedure and inappropriate to apply in humans at the current state of knowledge, a University of Washington scientist said at Stanford University School of Medicine Friday, May 4.

"Correcting genetic defects isn't easy," said Dr. Richard Palmiter, a biochemistry professor from the University of Washington. "We don't yet know enough to insert the gene into the proper location in the chromosome, and we don't know enough about gene products to predict all of their effects."

Ever since the "new genetics" burst onto the scene in the 1970s, people have speculated that diseases might one day be treated by transferring healthy genes into patients with defective ones.

But Palmiter made it clear that although rapid progress is being made, that day is not yet here.

Along with with five other prominent biological scientists who described how they are using the tools of the new genetics to probe the molecular basis of disease, Palmiter spoke at a daylong symposium at Stanford University School of Medicine.

Six featured speakers, all invited guests from around the country, detailed how new biochemical techniques are leading to a better understanding of diseases ranging from cancer to sleeping sickness.

The event was the Medical School's second annual symposium associated with the Program in Molecular and Genetic Medicine, a new school-wide research effort initiated by Medical School dean Dominick Purpura and involving faculty from both basic and clinical sciences. One goal of the research program is rapid translation of scientific advances into new medical methods of disease diagnosis and therapy.

The new techniques, that have ushered in a "biological revolution," permit scientists to dissect DNA, the genetic material, into pieces as small as individual genes. These pieces can be modified or reassembled into new molecules that can be used to probe the biochemical and genetic makeup of healthy and diseased cells.

Palmiter, with his colleague Ralph Brinster of the University of Pennsylvania, has been injecting human genetic material into mouse egg cells. The scientists have been studying in animals the gene transfer technique's potential for correcting genetic disease. In one series of experiments they observed a human gene's ability to overcome a genetic defect in mice. But where they corrected one problem, they created another, Palmiter reported.

The researchers used a special type of mouse with an inherited defect that causes the animals to grow to only half normal size. These mice have low levels of growth hormone, a body chemical that stimulates normal growth.

The scientists injected the gene for human growth hormone into mouse egg cells and found the animals that developed from these eggs grew to normal weight, or even exceeded the norm. However, all the females with the human gene were infertile, probably due to some unknown effect of human growth hormone on the mouse reproductive system.

Palmiter and his colleagues are also using the gene transfer technique to study how tumors develop in animals. They have found that insertion of a specific foreign genetic molecule into mouse eggs causes a brain tumor to develop in animals that grow from the genetically altered eggs. Using this gene transfer method to create cancer in animals may help identify the genetic elements that cause malignancy, Palmiter suggested.

Some genes that cause cancer have already been discovered. Most of the time they are normal segments of the genetic material, probably coding for proteins that play important roles in the cells and tissues in which they reside. But when acted upon by viruses, chemicals, irradiation, or other carcinogenic agents, these genes seem capable of turning a normal cell into a cancerous one.

The so-called "oncogenes" are feverishly under study by research groups around the country. About 20 such cancer genes are known, a handful of which are thought to be involved in human malignancy.

Dr. Mariano Barbacid of the Frederick Cancer Research Center spoke about one such oncogene called *ras*, which has been found in cells from some human tumors. Little is yet known about what protein the *ras* gene codes for and what might be its normal function, Barbacid said.

Although the *ras* oncogene has been found in human tumor cells, this is not proof that it causes human malignancy, Barbacid said. He and his colleagues are studying whether the gene is a causative agent associated with certain cancers in mice.

Analysis of oncogenes and their harmless counterparts has revealed precise biochemical differences between the two. The DNA double helix is made of chemicals called nucleotides strung together along two strands. Barbacid reported that a single change of nucleotides at a precise point in the gene is the only difference between the harmless form found in normal cells and the gene's almost identical twin found in cancerous cells.

Cancer is a major health concern worldwide. The study of parasitic diseases, prevalent in many of the world's undeveloped countries, has also been revitalized by the introduction of the new molecular and genetic techniques.

Dr. George Cross of Rockefeller University spoke about *Trypanosomes*, single-celled blood parasites that cause African sleeping sickness. The ribbon-like organisms, transmitted to humans through the bite of a tse-tse fly, have an unusual ability to biochemically "outwit" their host's immune attack. Like a criminal with a repertoire of "aliases" the parasite repeatedly switches the makeup of its protein coat, assuming a new disguise to stay one step ahead of the human's immune response.

Cross, who was the first to identify the group of proteins *Trypanosome* uses to cloak itself, said that scientists are beginning to seek answers at the molecular level to explain how the organism switches disguises. In some way, it shuffles hundreds of genes coding for coat proteins in its chromosome so that at any one time only one of the genes is active. This enables the organism to produce its repertoire of coat proteins in a highly regulated way.

Another blood disease is thalassemia, caused by a genetic defect in the oxygen-carrying molecule called hemoglobin, found in red blood cells. Dr. Thomas Maniatis of Harvard University and his colleagues are studying the molecular basis for this disease.

The hemoglobin molecule is composed of two types of protein chains, coded for by separate genes in the DNA. Single changes in the nucleotide sequence of the hemoglobin genes can cause thalassemia. Maniatis and his colleagues have found that many of these gene alterations affect the process by which the DNA is decoded in order to make protein.

In protein synthesis, the cell's machinery decodes genes by producing a template molecule called a messenger, made of ribonucleic acid (RNA). In order to work properly, the messenger RNA must be snipped apart and respliced at precise locations. Maniatis described how some genetic defects in thalassemia patients prevent hemoglobin messenger RNA from going through its correct splicing sequence.

Other symposium speakers discussed how the techniques of gene manipulation are opening up studies of the nervous system and development, the process by which multicellular organisms grow and develop specialized tissues for performing many different physiological tasks.

Dr. Charles Stevens of Yale University School of Medicine is studying certain protein molecules responsible for electrical activity in the brain. These proteins, embedded in the membranes of nerve cells, control the flow of electrically charged particles in and out of nerve cells. This flow of ions is the basis for neural impulses, the electrical signals that transmit information throughout the nervous system. Stevens said that the new biochemical techniques are enabling researchers to probe the molecular structure of these proteins.

Dr. Donald Brown discussed how genes can be turned on and off during different stages of the life cycle in multicellular organisms. He reported that he and his and colleagues at the Carnegie Institution of Washington have identified protein complexes that seem to mask and unmask portions of the DNA in developing frogs. When masked, specific genes are effectively hidden from the machinery that seeks to decode the genetic material into the proteins that carry out biological activities.

"We are entering a second revolution in molecular and cellular biology," Stanford University president Donald Kennedy declared in the opening remarks to the full house in Fairchild Auditorium.

"This country has a good basic science apparatus but the lag time for transfer to the bedside is long," Kennedy stated. In the second revolution, basic science advances must be translated into clinical progress, he said.

TWO REMAINING TALKS IN LECTURE SERIES

STANFORD—

"Inner World of the Bereaved Patient" is the topic of a lecture at 4:30 p.m., May 11, by Dr. Irvin Yalom, professor of psychiatry at Stanford University Medical Center.

The public lecture in the medical school's Fairchild Auditorium will be followed by a reception. All interested members of the community are invited to attend.

The lecture series—"Stanford Medical and Scientific Highlights," or S * M * A * S * H—is cosponsored by the medical school's Faculty Senate and the Stanford Medical Students Association.

The spring 1984 series will conclude June 1 with a talk entitled "Life in the Fast Lane: Cell Organelle Motility," by Dr. James Spudich, professor and chairman of structural biology, and Ronald Vale, a student in the Medical Scientist Training Program. Time and location remain the same throughout the series.

The Friday talks are intended to inform anyone with basic scientific understanding of significant medical research and developments at Stanford.

PLANNING COMMISSION APPROVES MODERNIZATION BUT NOT ZONING CHANGES

STANFORD—

The Palo Alto City Planning Commission unanimously recommended approval Wednesday for Stanford University Hospital's $110 million modernization project, but the commissioners declined to recommend zoning and land use changes which would facilitate parking and construction of a relocated Children's Hospital at Stanford.

The commission's action said the project as proposed by Stanford to modernize the hospital and replace outmoded facilities would have no significant impact on the environment. The City Council is scheduled to review the application for a land use permit on May 21.

In a parallel action, the city's Architectural Review Board, unanimously approved the design of the project Thursday and sent its recommendation to the city zoning administration, which will be granting the use permit for the project. The ARB has reviewed the building design several times previously.

During much of Wednesday night's three-hour public hearing, members of the Planning Commission questioned Stanford officials about a requested change in the city's comprehensive land use plan and zoning on two parcels along Welch Road. Stanford had wanted an existing parking lot parcel and a 3.06-acre site now partially used as a heliport changed from office research and housing to public facilities.

Elvia Garwood, director of the modernization project, has said that the change would facilitate moving parking spaces to the helipad site when construction displaces parking spaces.

"In a larger sense," Garwood said, "the changes would allow for logical future plans for Stanford hospital and intelligent planning for the area."

In addition, the changes would be consistent with the zoning and land use needed to relocate Children's Hospital at Stanford attached to the modernization project as currently planned.

"We're not turning down the merger or the potential move of Children's Hospital. We just feel in terms of the environmental document (that) we need more information to be able to make the finding," said commission chairman Helene Wheeler.

5-3-84

-more-

Wheeler said the commission would reconsider Stanford's request for a change in both the zoning and underlying land use plan if the institution would present additional evidence that such a change was needed to facilitate the project and would not harm the environment. But Robert Freelen, vice president for public affairs, said the university would not agree to a continuance of the matter, which would delay council review.

Freelen said after the meeting that while the commission's refusal to recommend a change in the zoning would not preclude relocating Children's Hospital, "it makes planning that much more difficult, since you are never assured during the planning process that the site you have selected will be approved."

Current plans call for moving the children's facility from its site across Willow Road to a location—as yet not precisely determined—adjacent to Stanford hospital's modernization project. Such a move would allow Children's Hospital patients to receive all services of the Medical Center without being moved by bus or ambulance from a distant facility.

The commission also recommended that council approval be granted on the condition that Stanford restrict parking near the hospital to Medical Center employees. Wheeler noted that Stanford would need to develop new parking regulations, since currently, the university makes no distinction between Medical Center and other Stanford employees when assigning parking permits.

It was a concern over housing that triggered much of the discussion at an April 18 commission meeting. The city's comprehensive plan earmarks the heliport site as multiple family residential, although the zoning has never been changed from office research. Wheeler and other commissioners had said that they would be reluctant to give up the housing designation there without assurances that Stanford would earmark another site for housing.

The state of California has already approved $85 million in tax exempt bonds to finance portions of the hospital's modernization project, which will provide more modern nursing units and other facilities, including a new surgical suite.

NEUROBIOLOGIST PATE SKENE NAMED SEARLE SCHOLAR

STANFORD—

Dr. Pate Skene, assistant professor of neurobiology at Stanford University School of Medicine, has been named a Searle Scholar by The Chicago Community Trust, a community foundation that administers the Searle Scholars Program.

One of 20 biomedical researchers to receive the Searle award in 1984, Skene will use the three-year $157,500 scholarship to support his research on the growth of nerve cells during brain development and nerve regeneration.

Skene, 29, did his undergraduate work at Vanderbilt University and received two doctoral degrees—in molecular biology and in neural sciences—from Washington University in 1980. Following postdoctoral positions at Stanford and Vanderbilt, Skene returned to the Stanford Medical School in 1983 as a faculty member.

Skene's research focuses on how the hereditary material, DNA, controls growth of axons, the long nerve cell fibers that conduct electrical signals through the peripheral and central nervous systems of animals. He is particularly interested in the regulation of a group of genes encoding proteins involved in axon growth during development and following injury.

The 1984 Searle scholars were selected from over 130 applicants—sponsored by 78 universities in the United States—who might be expected to make significant contributions to their chosen profession over an extended period of time, the Trust announced.

The Searle Scholars Program was established following the death in 1978 of Mr. John G. Searle, president of G. D. Searle and Co. an Illinois-based research and pharmaceutical company.

Since the program began in 1980, 67 awards totaling over $10,000,000 have been made in support of research in medicine, chemistry, and biological science.

WEIGHT-LOSS CAMP OPEN TO YOUNGSTERS

STANFORD—

Children ages 8-11 will be included for the first time in Stanford's summer weight-loss day camp, announced Dr. Mary Southam, the psychologist who runs the program.

The session for children is being added to the already established camp for teenagers on the university campus. The campers' aim is to have fun while slimming down through peer and parent support, and behavior modification in eating and exercise, Southam said.

The children's session will run from 1 to 4:30 p.m., four days per week, from June 25 through July 19. Lunch is not included. Swimming and active games, with the exception of tennis, will be emphasized.

Faculty will include members of the behavioral medicine program of the school of medicine. A fee is charged.

Early enrollment is recommended, as space is limited. For further information, call Southam at (415) 497-5065.

NURSES STRIVE FOR BETTER PAIN CONTROL

Editors: Photos available upon request if not included.

STANFORD—

A new system of helping patients with cancer and other illnesses control their pain is being tested by nurses at Stanford University Hospital.

The system, implemented this month in the hospital's general medical oncology unit, involves the traditional pain medications—analgesics—combined with hot and cold packs, massage, biofeedback, and relaxation techniques.

The approach is individualized to meet the needs of each patient and involves the patient more in decision making, said Leslie Jasper, a registered nurse participating in the program.

One innovative approach uses individually-tailored tapes produced by occupational therapists. A patient named Jane might hear a soothing voice tell her, "Close your eyes, Jane. Start counting backwards from 100, and at every 10th number wiggle your toes."

Ruth Miller, a leukemia patient, said she started using tapes while being given a medication that "gave me the shakes." She said, "I tried to concentrate on the tape rather than what was going on with my treatment, and it really helped a lot."

"What we're hoping to do is install a 'round-the-clock method of pain relief, while lowering patients' anxiety by giving them more control," Jasper noted.

She explained that several staff nurses became tired of repeatedly finding their patients in pain, and having little to offer in the way of satisfactory, sustained relief.

The new system of pain assessment developed by the nurses gives some responsibility for their own care to the patients. The idea is to determine the effectiveness of the various methods of pain control through the use of specially designed patient evaluation forms, as well as graphs for hospitalized patients' use.

Patients will use flow charts to plot out times of pain in relation to drug administration, radiation therapy, physical therapy, or other therapeutic activities.

With this formalized feedback, doctors, nurses and physical therapists should be better equipped to help each patient according to his or her own needs, Jasper said.

The pilot program to test the new pain assessment tools will be reevaluated after use with 40 patients, said Lily Mahony, the registered nurse who chaired the committee that worked for about two years to develop the new pain control standard. "Nothing is carved in stone," she said, indicating that the project, sponsored by the nursing department, may turn into a research study later on.

"By making independent judgments concerning patients' pain, nurses serve as vital members of the health care team not only in delivering patient care but also in educating and advising the physician members of the team concerning the development of better treatments," noted Dr. Thomas Raffin, assistant chief of medicine.

ROSENBERG TO RECEIVE 1984 KARNOFSKY AWARD FROM ONCOLOGY SOCIETY

STANFORD—

Dr. Saul A. Rosenberg will receive the 15th annual David A. Karnofsky Award from the American Society of Clinical Oncology (ASCO) at its annual meeting in Toronto, May 6-8.

Rosenberg, 56, is professor of medicine and radiology, and chief of the division of oncology at Stanford University School of Medicine.

The Karnofsky Award is the major annual award given by ASCO to a leading innovator in the field of oncology "who best exemplifies advances made in clinical oncology during recent years," the society announced.

At the Toronto meeting, Rosenberg will receive a a medal and present the Karnofsky Memorial Lecture, on the subject of new challenges and opportunities in understanding and treating low-grade lymphomas, cancers of the lymphatic system.

Rosenberg, who heads a major research program at Stanford Medical School focusing on the basic biology and clinical treatment of all types of malignant lymphoma, is best known for his pioneering work on one type of lymphoma called Hodgkin's disease.

In collaboration with the late Henry S. Kaplan of Stanford and other colleagues, Rosenberg helped develop an effective treatment strategy combining drugs, radiation and surgery, that has dramatically improved survival rates for Hodgkin's disease patients. Nearly 80 percent of these cancer patients, when properly treated, can now be cured of the disease.

Rosenberg, who has been on the Stanford faculty since 1961 and has led the medical school's oncology division since 1965, received his undergraduate and medical degrees from Western Reserve University. He is the recipient of numerous awards for teaching and research activities. Most recently, he was named an American Cancer Society Professor of Clinical Oncology.

The ASCO award is named in honor of David A. Karnofsky, a Stanford Medical School alumnus who died in 1969. Karnofsky, working at the Memorial Sloan-Kettering Institute in New York, was one of the leading researchers in the discovery and development of drugs for the treatment of cancer.

TWO MEDICAL SCHOOL FACULTY MEMBERS ELECTED TO NATIONAL ACADEMY OF SCIENCES

STANFORD—

Two faculty members at Stanford University School of Medicine are among 60 new members elected to the National Academy of Sciences (NAS), the academy announced Tuesday, May 1.

The two scientists are Dr. Stanley Falkow, professor and chairman of the department of medical microbiology, and Dr. Lubert Stryer, professor of structural biology.

Falkow, 50, is known for his work on the molecular biology of infectious diseases. He has done important research on genetic mechanisms underlying development of antibiotic resistance in microorganisms and has been instrumental in attempts to develop new vacccines against a wide variety of pathogenic agents.

Falkow became chairman of medical microbiology on his arrival at Stanford Medical School in 1981. Previously, he was on the medical faculty of the University of Washington. Falkow received his Ph.D. from Brown University in 1961.

Stryer, 46, is noted for his work on the chemistry of biological proteins. He has made original discoveries concerning the structure and dynamics of antibody molecules and certain pigments involved in vision. He has also pioneered new methods for investigating the rapid shape changes and motions of biological molecules.

Stryer, who was chairman of the department of structural biology from 1976 to 1979, came to Stanford Medical School in 1976 from Yale University. He received his M.D. degree from Harvard in 1961.

Election of the two Stanford scientists brings the total Stanford University faculty NAS membership to 78, of whom 17 are in the school of medicine.

ALCOHOL CLINIC PRESENTS LECTURE SERIES

STANFORD—

"Adult Children of Alcoholics" is the first of four public lectures to be presented by the Stanford Alcohol Clinic Thursday evenings this month.

The first talk, scheduled for May 10, will be given by psychologist Sharon Cushman of the clinic.

Other lectures of the spring series are:

- May 17—"Women and Alcohol," with psychologist Cynthia Soyster of the clinic;
- May 24—"The First Year of Recovery—Medical and Psychological Aspects," with Dr. Robert Landeen, assistant professor of psychiatry and medical director of the inpatient psychiatric unit;
- May 31—"Cocaine the New High," with psychologist Robin Press of the clinic.

The free lectures will take place 7:30 p.m. in room M104 of the medical school.

The alcohol clinic is part of the department of psychiatry and behavioral sciences at Stanford University School of Medicine.

For further information call (415) 497-6682, and ask for Diana Kennedy.

CROWLEY APPOINTS DEAN'S SEARCH COMMITTEE

STANFORD—

A faculty search committee to develop recommendations for the appointment of the next dean of the Stanford University School of Medicine was appointed Friday, June 22, by Vice President for Medical Affairs Lawrence G. Crowley.

The committee whose job is to find a successor to Dean Dominick P. Purpura will have its first meeting June 25.

"Because of the importance of this major effort I will chair the committee," Crowley wrote to the members. "It is my plan to put the search process on a fast track aiming at the appointment of a dean by September 1."

Purpura, a professor of neurobiology and neurology, will step down from the dean's post August 31 to return to teaching and research. However, he will continue to serve as an associate vice president for research at Stanford University Medical Center working on implementation of new research programs he helped develop.

The committee membership consists of Drs. Malcolm A. Bagshaw; professor of radiology; Helen M. Blau, assistant professor of pharmacology; Roland D. Ciaranello, associate professor of psychiatry; David A. Clayton, professor of pathology; Stanley Falkow, professor of medical microbiology; Willard E. Fee, Jr., associate professor of surgery; Thomas W. Feeley, associate professor of anesthesia (clinical); Rex L. Jamison, professor of medicine; A. Dale Kaiser, professor of biochemistry; James W. Raitt, clinical professor of medicine; and David K. Stevenson, assistant professor of pediatrics.

A medical student yet to be named will also serve on the committee, Crowley said.

Five individuals have been appointed as consultants to the search committee. They are Drs. Jack D. Barchas, professor of psychiatry and chairman of a former Dean's search committee; Albert Hastorf, vice president and provost; James Rosse, vice president and provost designate; Henry Riggs, vice president for development; and Gordon Holmes, president of the Stanford Medical Alumni Association.

THREE-DAY ANGIOPLASTY COURSE SLATED AT STANFORD

STANFORD—

Physicians will have an opportunity to attend an intensive three-day course to learn a technique which offers the possibility of replacing coronary artery surgery for many patients.

Multivessel angioplasty and advances in angioplasty equipment will be among topics covered June 25-27 at the Stanford Medical Center.

"Angioplasty is rapidly eclipsing coronary artery surgery for coronary artery disease," said Dr. Stephen Oesterle, director of the Unit for Coronary Interventions at Stanford and a course organizer.

In angioplasty, catheters inserted in a leg artery are threaded up to the heart. A "balloon catheter" is then inflated in a coronary artery narrowed by atherosclerotic deposits, flattening the deposits and opening the clogged vessel without surgery. The course, "Guide Wires in Coronary Angioplasty: Basic and Advanced Techniques," will feature lectures and live television and audio transmission of angioplasty cases.

Wednesday, June 27, Dr. Geoffrey O. Hartzler, consulting cardioloist of the Mid-America Heart Institute in Kansas City, will speak at 8:30 a.m. on "Multivessel Percutaneous Transluminal Coronary Angioplasty."

Other faculty include Oesterle, Dr. Donald C. Harrison, chief of the division of cardiology at Stanford, Dr. John B. Simpson of Sequoia Hospital in Redwood City, Dr. David Faxon, associate professor of medicine and director of the cardiac catheterization laboratory at Boston University Medical Center, and others.

COMMUNITY FUNDRAISERS TURN OVER MONEY TO HELP CHILDREN

STANFORD—

Francis Hinson didn't use all the money friends raised to help him pay off his medical bills, so the surplus has been turned over to Stanford University Hospital (SUH) to buy amenities for pediatric patients and their families.

At a brief ceremony June 15 in the children's playroom, Harry Simanek and Susan Rapp of the "Friends of Fran" organization presented Community Relations Director Jeanne Kennedy with a check for $10,000.

"Fran was an enigma," said Simanek. "He was very particular about how any money be raised . . . He had always insisted that he be allowed to pay us all back."

Friday's ceremony, Simanek said, was a symbolic opportunity for Hinson to pay back the friends and neighbors who had contributed the money Hinson had always regarded as a loan.

Hinson, a lifelong Palo Alto resident who was also widely known locally through the downtown smoke shop he operated for several decades, became heavily in debt in 1982 following lengthy hospitalization for a cardiac condition.

Simanek, vice president of the Boston Company, Inc., and his associate Susan Rapp, formed the "Friends of Fran" organization to raise money and serve as trustee to help Hinson pay off his medical bills. About $25,000 was raised through sale at $100 each of signed prints by local artist Marguerite Fletcher depicting Hinson outside his smoke shop.

In addition both SUH and the Palo Alto Medical Foundation agreed to reduce portions of the bill. The total amount was not made public.

The surplus was achieved after Medicare agreed to provide coverage for much of Hinson's bills retroactively.

Hinson was aware before his death at SUH May 12 that his debts were liquidated by Medicare, Social Security, and the fund, Simanek said.

Simanek said he asked Hinson, "'when this is all cleared up and your's debt free, how do you want the money to be used.'

"He told us, 'I would like it to go to people who had heart problems, particularly children.' He wanted to be a contributor himself."

Dr. Irving Schulman, chairman of the department of pediatrics, said the money would be used to buy such amenities as new chairs and games for the playroom, and furniture to increase the comfort of parents who must spend long hours waiting with their often desperately ill children.

SCULPTURE HONORING CANCER PIONEER PLACED IN FRONT OF HOSPITAL

Editors: Photos of the sculpture, alone or being installed by workmen, available on request if not included.

STANFORD—

A sculpture by renowned Cubist Jacques Lipchitz has been placed in front of Stanford University Hospital as a memorial to Dr. Henry Kaplan, internationally renowned radiologist and cancer research pioneer, who died Feb. 4.

The aluminum cast of the 17-foot sculpture, "Song of the Vowels," was positioned in the grassy area in front of the hospital on June 12 at an angle intended to optimize the effect of sunlight on the work. A fundraising effort has been underway to meet the $350,000 cost of the sculpture.

"As an artist, Lipchitz is world class and so is "Song of the Vowels," said Albert Elsen, professor of art history, and a member of the committee which selected the work to honor Kaplan.

"Dr. Henry Kaplan, this university's greatest cancer specialist, deeply admires and identifies with Lipchitz's "Song of the Vowels" which would make its presence on this campus near the hospital all the more valuable and appropriate to honor him," Elsen wrote in January, shortly after Kaplan learned he was dying of cancer.

Lipchitz, who died in 1973 at age 82 said he had decided to create "Song of the Vowels in 1932, because "'I had decided to attempt a monument suggesting the power of man over nature,' " Elsen wrote.

" 'I had read somewhere about a papyrus discovered in Egypt having to do with a prayer called the 'Song of the Vowels,' a prayer that was a song composed only of vowels and designed to subdue the forces of nature," ' Elsen quotes Lipchitz in a January letter recommending purchase of the sculpture.

Kaplan, co-inventor of the first medical linear accelearator in the Western hemisphere, said shortly before his death that he thought one of his greatest accomplishments was helping to develop a treatment program which turned Hodgkin's disease, a cancer of the lymphatic system, from an almost universally fatal to a usually survivable malignancy.

Elsen sees parallels between both Lipchitz's and Kaplan's desire to triumph over forces of nature. The sculpture, Elsen said, celebrates (Lipchitz's) optimism about humanity's power to triumph over adversities encountered in nature." He said both the artist and Kaplan shared "awesome intellects employed for compassionate purposes."

The cast now on display was made by Lipchitz for his own home in Italy, where it remained for many years. It had originally been commissioned in 1931 by a wealthy French woman who wanted a large work for her garden. Other casts are on display in front of the Pompidou Center in Paris, and in the sculpture gardens of Princeton and UCLA.

Graphically, the sculpture depicts the theme of twin harpists, another interest of Lipchitz, who said he had been inspired by a performance in a French concert hall.

In the tradition of Cubism, the work attempts to conjoin inanimate objects and humans "to create a healing or more humane art that evoked life's unities and to invest sculpture with a fresh poetic power that made it more responsive to intuitive experience," Elsen said.

A formal dedication of the sculpture will be scheduled in the Fall.

FOR IMMEDIATE RELEASE

HOSPITAL LAUNCHES HOME CARE PROGRAM

STANFORD—

A home care program to help Stanford patients after release from the hospital will be submitted to the state for final certification after having been approved by the board of hospital directors Wednesday, June 13.

Sheldon King, director and executive vice president of the hospital, said he hopes the program can begin serving the first patients in San Mateo and Santa Clara counties by the end of the year.

Conceived as a department within the hospital, the program will be comprised of teams of registered nurses, home care aides, physical and occupational therapists, social workers, volunteers, and a dietary consultant. A coordinating group will plan patient care based on referring physicians' orders, and those staff members needed will visit patients' homes after discharge from the hospital.

"Our motivation is to provide continuity of care for our patients," said Dr. Lois Welches, R.N., associate director of nursing, who directed the feasibility study for the program. "We've noticed over the past couple of years that patients' length of stay in the hospital is shortening, while the overall level of acuity is rising. Patients go home with many physiological, social and emotional needs."

At the same time, Medicare's new system of DRG (diagnostic related groups) classification for prospective reimbursement, as well as other trends in third-party payment for health care, have made it necessary to look for alternatives to expensive inhospital treatment whenever possible, without sacrificing quality of care, Welches said.

"Insurance companies are becoming increasingly interested and willing to pay for home care," she noted. Medicare will also pay for some services, although coverage is limited to specific types and numbers of visits.

King said a survey indicated that about one-third of local patients would benefit from home care services and that many of these patients were not referred to existing home care agencies "for a variety of reasons."

He added that physicians and patients will retain all options to use the home care program of their choice.

"We'll continue to refer patients to outside agencies as appropriate," Welches said, especially since the Stanford program will "start small."

6-19-84

-more-

King noted that some patients, such as pediatric and transplant patients, have specialized needs for which most existing agencies do not provide services. The new program, which will provide 24-hour on-call service, is tailored to the needs of all Stanford patients, said Welches.

"Some special services will help patients who need TPN (total parenteral nutrition), respiratory therapy, or IV therapy at home, or cancer patients undergoing chemotherapy who need help with nutrition, avoidance of complications, mobility, adjustment to the disease as well as to being at home, and employment. We'll be assisting the families as well," she said.

The majority of Stanford Hospital patients needing home care fall into the diagnostic categories of perinatal, circulatory system disorders, carcinomas, and musculo-skeletal system disorders, Welches said, though diagnosis is not a major criterion for assessing potential home care patients.

A hospice service, allowing the terminally ill patient to die comfortably at home, will be offered as part of the program, she noted.

First-time mothers, as well as parents of infants who've been in the intensive care nursery, are prime candidates for the program, to help them make the transition from hospital to home more smoothly.

The home care program will be staffed on rotation, Welches said, from among a pool of relief staff already employed by the hospital as well as by some permanent personnel, all to be trained in the special techniques of home care—which includes both direct help and teaching and/or monitoring.

"This will have multiple benefits," she said, "by allowing a better use of our nursing staff, whose census has been low, as well as providing staff with a greater sensitivity to patients' needs when they return to work inside the hospital."

Also, she pointed out that expert nurses in specialized fields will be available to the home care program as needed "on very short notice."

A medical director and a medical advisory committee composed of faculty and community physicians will provide medical direction, and a search is under way for an assistant director of nursing to head the department, Welches said.

The medical director will collaborate with the department of family, community, and preventive medicine and the department of medicine, in the development and implementation of a teaching program for residents and students who elect to rotate through the department of home care.

(EDITORS: This release, an updated version of a January 24, 1984 story, is being sent out in response to the continuing need for volunteers to participate in hepatitis B studies. Dr. Merigan is available for interviews at (415) 497-5715.)

FOR IMMEDIATE RELEASE

FDA APPROVES HEPATITIS B STUDY PROTOCOL USING NEW INTERFERON DRUG

STANFORD—

Stanford University Medical Center scientists are ready to begin treating chronic hepatitis B patients, following approval by the Food and Drug Administration, with a new genetically engineered interferon drug that they think may be more effective than other medication in controlling the disease.

The drug, called beta-ser fibroblast interferon, is one of only a few interferons manufactured by recombinant DNA techniques to be used in treating the incurable liver ailment.

The research team, led by infectious disease specialist Dr. Thomas Merigan, believes the drug may be given in large doses to decrease the amount of the hepatitis B virus in the bloodstream on a long-term basis. Previously tested interferons did lower the amount of virus in the bloodstream, but only during the time period in which the patient was being administered the drug, Merigan said. Genetic engineering has made the new drug more stable, he continued, which hopefully will lead to long-lasting loss of the virus.

Hepatitis B is a unique virus that causes infection of the liver, Merigan said. There is no cure for the disease, which afflicts more than 100 million people worldwide. The virus can be found in all of the body's secretions and fluids, and can be spread by intimate contact or by contaminated medical or dental instruments. Population groups considered at high risk include hemodialysis patients, medical or dental workers, gay males, and users of illicit intravenously-administered drugs.

6-18-84

-more-

Various therapies for the disease have been undergoing clinical testing at Stanford for about 10 years. Interferon, a protein the body produces naturally in minute amounts that increases the defense system against malignant cells and viruses, was first incorporated in hepatitis B treatments in 1974. Initially hailed as the "cure-all wonder drug" by scientists in 1978, only with the development of recombinant DNA techniques in 1980 did interferon become available in quantities large enough to be considered practical and affordable. Cetus Corporation and Triton Bioscience Inc. are contributing the new interferon drug for these studies.

Patients interested in volunteering to participate in the clinical testing of the new drug must be between 21 and 65 years of age. They must be carriers of the virus for at least 12 months. All participants must have a liver biopsy that must show chronic hepatitis B.

Those accepted into the study will receive daily intravenous injections of different doses of interferon for one week of each month for four months.

The researchers are also seeking hepatitis B patients to participate in an ongoing clinical trial of a drug called adenine arabinoside monophosphate (Ara-AMP). Scientists have been testing this drug since 1981 to see how effectively it causes a permanent decrease of the virus in the bloodstream, improves the liver disease, and lessens the ability of patients to infect others, according to Dr. Gabriel Garcia of the gastroenterology division.

To qualify to participate in the trial, patients must be between 21 and 60 years old. They must be carriers of the hepatitis B virus for at least 12 months, and a liver biopsy must show existence of the virus. Scientists must also be able to determine how much virus is in the bloodstream through blood tests.

Because both drugs under study are experimental, some side effects may be encountered, Garcia said. These may range from nausea and vomiting to pain in the feet and lower legs, rarely accompanied by weakness of muscles. All side effects, Garcia pointed out, tend to disappear after treatment is stopped.

Participants are requested to commit themselves to the study for two years. They will receive treatment for five months, and will be under observation for the remaining 19 months.

To inquire about either study, call Stanford's hepatitis research clinic at 415-497-6231.

ASSOCIATE DIRECTOR UTT RETIRES FROM SECOND CAREER AT SUH

STANFORD—

Don Utt, whose Stanford University Hospital management career has spanned nearly two decades, is scheduled to retire June 29 as associate director.

On June 13, the hospital board passed a special resolution honoring and thanking Utt, 57, for his 18 years of "excellent service to the hospital."

"Don Utt has done more than any other individual to provide continuity of leadership at Stanford University Hospital," said hospital director Sheldon S. King. "Don has provided an invaluable thread of consistency during multiple transition periods and has served as a model of integrity, earnest efficiency and loyalty to Stanford. He will be missed," King continued.

Civilian hospital administration was Utt's second career. When he arrived at SUH in 1966 he had just retired after 23 years in the military where he started as an enlisted medical corpsman.

His first job at SUH was as department manager in charge of linen, mail, transport and related functions. Now he is the administrator with responsibility for many of the ancillary support functions, including the cluster of departments he once ran.

Utt served in 1981 as acting hospital director before the arrival of King.

Utt said he and his wife, Donna, plan to travel for several months. Then they plan to spend time between their Cupertino home and their second home in the Sierra.

MEDICAL SCHOOL GRADUATES TOLD PHYSICIAN ROLES ARE CHANGING

STANFORD—

Stanford Medical School graduates were told Sunday they are becoming doctors in a pivotal era when physicians are losing their preeminence to those who control health care finance.

"This generation, thus, is reared between the period of physician (as) royalty and the period in which physicians will be regulated, organized and third-party controlled," said Dr. Robert A. Chase, professor of surgery. He gave the Medical School's commencement address to a smaller-than-usual crop of new Stanford M.D.s, other health and science professionals, and families.

"Because of a concern for cost, coupled with new attitudes toward physicians, it's clear that the physician control of medical practice is waning," he said.

Chase, contending that "the cost of health care is medicine's hottest problem," said physicians are often held solely responsible for exploding health care costs. He said these costs have risen from an expenditure of $43 billion in 1965 to an estimated $438 billion in 1985.

But "physicians alone are not responsible for escalating costs. Blame should be shared with third parties, lawyers, and the patients.

"Patients become indifferent to cost—a patient whose costs are covered by a third party is likely to choose the most elaborate not the most conservative provider," Chase said. "Therefore, the physician gains no patient because of conservative and efficient ways."

Chase said many changes have occurred during his career:

"At the time I graduated (from medical school at Yale in 1947) , I considered the last reigning monarch, except for the captain of an ocean-going liner, to be the chief of medicine or chief of surgery in the medical center.

"Those crowns of power now sit on the heads of hospital administration, director of third-party payers, and government officials," he added.

The new physicians will be faced with "a new stressful choice of giving or denying care based solely on the financial consequences of what action is taken.

The 66 new physicians, who picked up their diplomas clad in traditional cap and gowns, represented the smallest number of M.D. graduates in at least 10 years, said Charlotte Crucean, medical school registrar.

JUNE 18, 1984

-more-

She said that while medical school classes have remained fairly constant, a larger number of students have recently been encouraged to stay an additional year to pursue research or to take a year off during their studies for practical clerkships. The 1985 class, Crucean said, is expected to return to normal levels when the students who would have graduated this year will do so. In 1983, 91 new M.D.s were graduated, in 1982, there were 81.

In addition to M.D. degrees, 22 students received Ph.D degrees in nine separate fields, ranging from biochemistry to hearing and speech sciences. Thirty-eight students received master of arts degrees in physical therapy, three students received master of science degrees, and 10 students were given bachelor of science or bachelor of arts degrees in basic medical sciences and medical microbiology.

A total of 102 graduates personally picked up their diplomas, Crucean said.

A new award, the Alwin C. Rambar Award for Excellence in Patient Care was presented posthumously to cancer pioneer Dr. Henry S. Kaplan, professor of radiology. Kaplan's widow, Leah, accepted the award from Dr. Lawrence G. Crowley, vice president for medical affairs.

Twelve faculty members were honored Sunday for teaching excellence.

Receiving the Henry J. Kaiser Family Foundation Award for Outstanding and Innovative Contributions to Medicine were Stanley Falkow Ph.D, professor and chairman of the Department of Medical Microbiology and Dr. Halsted R. Holman, professor of medicine (immunology). This was the first time that the award, decided by a vote of the faculty, was given to two faculty members.

Other faculty awards, all chosen by a vote of medical students, included the Henry J. Kaiser Foundation Award for Excellence in Teaching. For preclinical education, students in the basic sciences voted awards for Dr. Carlos Camargo, associate professor of medicine (clinical); Dr. Lawrence H. Mathers, lecturer in surgery-structural biology; Carla Shatz Ph.D., assistant professor of neurobiology; and Dr. Lubert Stryer, professor of cell biology.

The Kaiser awards for clincal teaching went to Dr. Norman Blank, professor of radiology; Dr. Lawrence Crapo, assistant professor of medicine; Dr. Michael D. Amylon, assistant professor of pediatrics; Dr. Bertil E. Glader, associate professor of pediatrics; and Dr. Thomas A. Raffin, assistant professor of medicine (respiratory medicine).

Dr. Keith I. Marton, assistant professor of medicine (general internal medicine), received the Arthur L. Bloomfield Awrd in Recognition of Excellence in the Teaching of Clinical Medicine.

The Lucille Daniels Recongition Award for Outstanding Contribution to Physical Therapy at Stanford was given to Ann Hallum, senior instructor.

HEART/LUNG TRANSPLANT PATIENTS RECEIVES SECOND SET OF ORGANS

STANFORD—

Transplant recipient Charles Walker was given a second set of heart and lungs at Stanford Medical Center Sunday after the lungs he received more than three years ago became damaged beyond repair by rejection.

The operation was the first time a heart and lung has been replaced for the second time in the same patient, said Dr. Stuart Jamieson, head of Stanford's heart/lung transplant program.

Retransplants for patients who have received only hearts have been performed on 22 of the 304 patients transplanted since January 1968 at Stanford. Two heart-only transplant patients have been retransplanted twice.

Walker, 33, originally from Binghamton, N.Y., was reported in critical but stable condition Monday following an eight hour operation which began about 1 p.m. Sunday. The surgical team was headed by Jamieson, an assistant professor of cardiovascular surgery.

Walker, who on May 1, 1981 became the second person to receive a heart and lung combined transplant at Stanford, had been in intensive care since April 20. His lungs had been so badly damaged by rejection, Jamieson said, that they were incapable of supporting life. During the latest hospitalization, Walker was capable of breathing only with the help of a respirator.

Jamieson said the retransplant offered Walker his only prospect of returning to a life without a respirator. The operation was complicated by scar tissue from his previous surgery, which potentially could have increased the amount of bleeding, the surgeon explained.

June 18, 1984

-more-

Although doctors were encouraged, Jamieson cautioned that "Mr. Walker is at increased risk from the surgery because the medication he took to prevent rejection will make him more susceptible to infection in the first few weeks after surgery."

Walker's heart was undamaged, disproving an earlier theory that rejection in the heart and lungs would always occur in tandem, Jamieson said. "Work in the laboratory using animals had indicated that this pattern of rejection could occur, and that enabled us to diagnose Mr. Walker's condition," Jamieson said.

Nineteen patients have received new hearts and lungs at Stanford since March 9, 1981. Thirteen of the patients are alive, including the first. Three heart/lung transplants were performed between 1968 and 1971 at other institutions, but no patient lived longer than 23 days.

The advent of more sophisticated immunosuppresives—which allow healing of the windpipe—encouraged Stanford to revive the procedure three years ago. Since then about a half dozen institutions worldwide have begun performing heart/lung transplants.

Walker had suffered from a congenital heart defect. His physical ability was limited throughout his life, and eventually his poorly pumping heart caused lung damage as well. By the time he received his first heart and lungs, doctors had given him less than a year to live.

After his first operation and until his recent illness, Walker, trained as a mortician, had been extremely active, working as a counselor for a funeral parlor and as a cashier in a liquor store.

He had decided to move to California during his post-operative recovery period. He frequently counseled potential heart and heart/lung transplant patients and their families.

REAGAN APPOINTS KORN CHAIRMAN OF NATIONAL CANCER ADVISORY BOARD

STANFORD—

Dr. David Korn has been named chairman of the National Cancer Advisory Board (NCAB), a 29-member advisory panel to the director of the National Cancer Institute (NCI), The White House announced Friday (June 15).

Korn, professor and chairman of the department of pathology at Stanford University School of Medicine, had been named in May by President Ronald Reagan to a six-year term on the NCAB.

Friday's NCAB chairmanship appointment is for a two-year term, effective immediately through March 9, 1986, the White House announcement said.

The National Cancer Advisory Board, which meets at least four times a year, assists the NCI director with activities of the National Cancer Program, the United States' comprehensive effort aimed at combating cancer.

One of the Board's major responsibilities is approval of research grants awarded by the National Cancer Institute, which in 1983 totaled nearly $600 million.

As NCAB chairman, Korn succeeds Dr. Tim Lee Carter, a physician from Kentucky, the NCI said.

Korn, who received both his undergraduate and medical degrees from Harvard University, has been on the Stanford Medical School faculty since 1968.

A researcher noted for his work on the enzymatic control of DNA replication, Korn has written numerous articles and is editorial board member of the *American Journal of Pathology* and *Human Pathology*. He is also a member of the board of directors of the California Society of Pathologists and serves on several other professional boards and councils.

Korn has previously served as an advisor on cancer to the federal government. He was a member of the Board of Scientific Counselors, Division of Cancer Biology and Diagnosis, National Cancer Institute, from 1977 to 1982, serving as chairman from 1980 to 1982.

HOW AN ORTHOPEDIC SURGEON EVALUATES HIS PROFESSION

STANFORD—

When orthopedic surgeon David Schurman arrived at Stanford from UCLA eleven years ago medical technology was undergoing a major breakthrough.

"Total hip and other joint replacements had just been introduced," he recalls. "By the time I had entered academic medicine full time, more than 100,000 operations had been performed in the United States alone. The artificial joints often broke, wore out, loosened or caused infections. The technology was badly in need of scientific assessment which was not being done."

He decided to look into it and today, thanks to his efforts, orthopedic surgeons at Stanford and elsewhere have a sophisticated computerized system for auditing results and sharing data to make joint replacements safer, less costly and more effective.

"Translated in patient care terms," Schurman adds, "this means longer, trouble-free existence for arthritis victims who have had replacement surgery for worn-out, painful joints.

Schurman specializes in joint replacement surgery of elbows, shoulders, hands, hips, knees and feet.

His computer data bank, called the Standard Orthopedic Arthritis Record, or SOAR for short, was developed in conjunction with Stanford computer scientists to provide a common "language" or rating system that all orthopedic surgeons can use.

The system can audit results within an institution, ranging from the effectiveness of the surgery itself to the devices used and differences in outcome among the patients of individual surgeons. The system has been adopted by the Hip Society, made up of the country's leading orthopedic surgeons, and implemented at the Brigham and Women's Hospital and Massachusetts General Hospital, Boston; the University of California, Los Angeles; and Mayo Clinic, Rochester, Minnesota.

"The system allows patients to rate themselves," says Schurman. "It's better to have the patients fill out the questionnaires than their physicians who may or may not remember a lot of personal details."

The forms are completed when the patients are examined prior to surgery. The questions asked include how much pain the arthritis is causing, how far the patients can walk, whether they use canes or crutches or how often they go out of the house. Three and six months as well as a year after the operation the patients are evaluated again. Comparisons are made of their X-rays, health status and personal impressions as to how they have benefitted from artificial joints by age, sex and type of disease.

The information is useful to orthopedic surgeons in selecting patients for future operations.

Schurman explains:

"We know, for example, that people with severe rheumatoid arthritis who have had total hip or knee replacement almost never require repeat surgery. Because they are in poor health they seem to make fewer demands on their joints than active or overweight patients who have a higher failure rate.

2-2-2 "Pain-relief obtained by the procedure is identical across all ages with different forms of arthritis. These would have been reasonable assumptions, but they had never been demonstrated before."

The system gathers information on the strengths or weaknesses of the artificial joints themselves so that technical improvements can be recommended to manufacturers.

"To require any kind of joint replacement," Schurman notes, "the patient must have significant cartilage damage. Since the ligaments are usually intact, one approach for repairing the knee joint is to resurface the worn out ends of the two connecting bones with artificial materials. Another approach is connecting them with a balky piece of apparatus that resembles a door hinge somewhat similar to the crude kind used in the movie about Dr. Frankenstein's monster.

"The resurfacing technique failed initially. The hinged joints faired better. But as more hinge-knee operations were done during the 1970s, their infection rate was discovered to be unacceptably high. What followed was an all-out effort to develop better resurfacing prostheses. The new types use durable alloys——titanium or vitalium——and their failure rate is below one percent."

Loosening up of artificial hip prostheses has been another failure. This problem is also being solved by improved design and materials, including a new bone cement.

But the field of hip replacement, as Schurman sees it, is in a state of transition. People are exploring alternative systems, one of them being the use of porous ingrowth materials whose surfaces allow bone to grow into them resulting in biologic fixation.

"This is the most exciting area today because it's different,' he says. "but it's also unproven and requires carefully designed clinical trials such as those now being conducted at the University of California in San Francisco.

Schurman, who received his medical degree from Columbia and his undergraduate education at Yale, says he was attracted to his specialty because his cousin was an orthopedist and looked happy with his work.

"All the things he told me about orthopedic surgery were true," says Schurman, "and one of them was that the patients you deal with always get better.

"Most of my patients have arthritis of multiple joints. It's a progressive disease, but in my dealing with them they get better. They get excited when they find out how surgery can make their joints work again as well as they did before they became incapacitated."

In addition to evaluating surgery, Schurman has been working with associate professor Dennis Carter and professor Robert Piziali in Stanford's department of mechanical engineering to design better artificial joints.

Schurman and his colleague R. Lane Smith, a molecular biologist, are also looking into the biochemistry of cartilage destruction.

"Once cartilage is damaged it never grows back," Schurman explains. "The ultimate treatment for cartilage-worn joints would be to give the patient something that would help the cartilage repair itself. Salamanders and newts will regenerate an entire limb if you cut it off.

"There is every reason to think that vertebrate animals also are capable of regenerating cartilage. There are potential answers in the far distant future which can be provided by basic research."

It was also basic research in Schurman's laboratory several years ago that demonstrated in animals the therapeutic potential of total lymphoid irradiation for patients with rheumatoid arthritis.

Schurman's work is supported by grants from the National Institutes of Health partly in conjunction with the Stanford Arthritis Center, one of 18 federally funded multi-purpose arthritis centers across the country. The centers emphasize public education as well as research into the causes and treatment of arthritis.

CONFERENCE COVERS NUTRITION FOR EXPECTANT MOTHERS

(Editors, news directors: Although the nutrition conference described here is intended for health professionals, reporters are welcome to attend sessions and to schedule interviews with speakers. Conference organizer Jo Ann Hattner, a Stanford University Medical Center nutritionist, may be reached for information or to request interviews at (415) 497-7309.

STANFORD—

"Nutritional Care of High-Risk Obstetrical Patients and High-Risk Infants" is the topic of a three-day conference beginning Wednesday (June 20) in Fairchild Auditorium at Stanford University Medical Center.

Visiting speakers Wednesday morning include Michael A. Simmons, professor and chairman, department of pediatrics at the University of Utah School of Medicine, who will present an "Update on Fetal Nutrition."

Janet C. King, professor of nutrition, department of nutritional sciences at the University of California at Berkeley, will give an "Update on Maternal Nutrition," while Bonnie Worthington-Roberts, professor of nutritional sciences and chief nutritionist at the Child Development Center of the University of Washington at Seattle will discuss "Cravings and Aversions During Pregnancy."

Additional speakers and workshops will continue through Wednesday afternoon.

The program, presented by the departments of pediatrics, gynecology/obstetrics, and dietetics, is intended to teach health care professional's about the nutritional needs of women during high risk pregnancy and during their new baby's infancy. The conference is also expected to inform about the nutritional needs of the immature and ill newborn, according to the program brochure.

STANFORD MEDICAL SCHOOL DEAN RESIGNS

STANFORD—

Dr. Dominick P. Purpura, 57, has asked to be relieved of his administrative responsibilities as dean of the Stanford University School of Medicine, effective August 31.

In his letter to Vice President for Medical Affairs Lawrence G. Crowley, Purpura cited "a desire to return to neuroscience research and educational programs in basic neurology."

Purpura is a professor of neurobiology and neurology at Stanford. He said "he sees the development of research on fundamental mechanisms of brain function as a major challenge for his future academic activity."

In accepting Purpura's resignation, Crowley announced that the noted brain researcher will also remain as associate vice president for research at the Stanford University Medical Center.

In a joint statement, Stanford University President Donald Kennedy, Vice President and Provost Albert H. Hastorf, and Crowley said they were very pleased that "Dr. Purpura would continue to provide leadership in the development and implementation of new research programs in the Medical School, an area in which he has been outstanding."

Crowley said he would announce the appointment of a dean's search committee soon.

Purpura is credited for several accomplishments during his 26-month deanship. According to Crowley, he is responsible for the concepts of the proposed Center for Molecular and Genetic Medicine and the Nuclear Magnetic Resonance Center, projects which are of high priority for the future academic programs of the Medical School.

6-12-84 -more-

Purpura created a new Office of Education under associate Dean Robert Cutler to monitor and evaluate the School's education program. He attracted the Kaiser Foundation Chair in Health Policy Research as a mechanism for insuring a central role of health policy and planning in the Medical School, and he has been responsible for the construction of the first $12-million phase of a new animal facility and program in animal laboratory medicine.

During his administrative tenure, Dean Purpura participated actively in neurobiology teaching at the Medical School and Stanford's Human Biology Program.

"He has invigorated the teaching program by his own excellent teaching and has stimulated a similar thrust and interest in teaching among the medical faculty," Crowley said.

Among his accomplishments, Purpura also singled out "the new spirit of student-faculty-alumni and staff cooperation, alumni programs, and the formulation of the medical center's fund-raising agenda."

Purpura became dean at Stanford in 1981, coming from the Albert Einstein College of Medicine in New York where he chaired the Department of Neuroscience, and directed the Rose F. Kennedy Center for Research in Mental Retardation.

He has continued to serve as editor-in-chief of *Brain Research, Developmental Brain Research,* and *Brain Research Reviews,* and has contributed to reports for the Congressional Office of Technology Assessment and the U.S. Senate on future opportunities in neuroscience.

In 1983, Purpura was elected to membership in the National Academy of Sciences for his research related to abnormal nerve cell development in mental retardation. He also served as president of the Society of Neuroscience and is the current chairman of the International Congress Committee of the International Brain Research Organization of the World Federation of Neuroscientists.

HOSPITAL NAMES PATIENT RELATIONS COORDINATOR

STANFORD—

Donna Pronko has been named patient relations coordinator of Stanford University Hospital effective June 4, announced Jeanne Kennedy, director of community relations.

Pronko comes to Stanford from a position as training manager for Benham Capital Management Group, a money market fund. She has worked at the hospital before, as an education and development specialist in the human resources development department, from 1979-82.

The patient relations program of the department of community relations has been operating since June of 1980. The new position was created in response to a need for a full-time liaison—particularly on the nursing units—between hospital staff and inpatients, said Kennedy.

One of Pronko's goals is to switch from reacting to problems as they occur, to anticipating and preventing them. She hopes to work across departmental lines to find solutions, she said. She will be working closely with the 16 patient relations associates, who make up the volunteer arm of the program.

"Donna will be well positioned to detect patterns of problems as well as specific problems," Kennedy said.

Pronko, originally trained as a medical technologist, has a B.S. in chemistry from the University of Alberta, and an M.P.H. degree in health education from San Jose State University.

She can be reached at (415) 497-7167 or 497-7168.

SMOKERS CHEW THEIR WAY TO QUITTING, THROUGH THERAPY

STANFORD—

A combination of a newly available nicotine chewing gum and behavior therapy is the most effective way currently known to help smokers quit, says a Stanford psychologist who tested the dual method and now intends to offer it to patients on a regular basis.

In a recent study comparing nicotine gum and behavior therapy, alone and in combination in a sample of 60 smokers, the combination was proved superior to either method alone, and to other methods which normally result in about 75 percent relapse rate, said Dr. John Bachman, director of the behavioral medicine clinic at Stanford University Medical Center.

Immediately after six weeks of treatment, Bachman said, 86 percent of those receiving the combination had stopped smoking. Only 64 percent of those using the gum and 55 percent receiving behavior therapy had stopped.

One year after treatment, 50 percent who had received the combination versus 23 percent who'd received the gum, and 30 percent who'd received behavior therapy remained nonsmokers, he said.

The research, to be published in *Behavior Therapy*, was funded by Merrell Dow, the pharmaceutical company that markets "Nicorette," the nicotine gum. It was the doctoral dissertation of Joel Killen, now a research associate with the Stanford Heart Disease Prevention Program, with coauthors Drs. C. Barr Taylor, assistant professor of psychiatry, and Nathan Maccoby, emeritus professor of international communication.

Based on the results, Stanford's behavioral medicine clinic is expanding its stop-smoking program to include the multifaceted approach, said Bachman, a clinical instructor of psychiatry.

Both at Stanford and several other institutions including University of California at San Francisco, the combination approach has been shown to work, said Killen, "probably because smoking involves not only psychological but also pharmacological dependency, and one must address both variables in order to help smokers quit and *stay quit*—that's the hard part."

Nicorette, available only by prescription, was approved by the FDA in early 1984 as an aid to weaning smokers from their cigarette habit.

The gum offers a different route of administration for nicotine, the addictive ingredient in cigarettes though not the most harmful agent, scientists say. Patients are instructed to chew the gum only when they experience a distinct craving for a cigarette; thus right away, many "superfluous" smoking times are cut out.

Then, Bachman explained, as the dose tapers off the body gradually adjusts to nicotine's absence, as it would for any addictive drug.

-more-

6-11-84

Devised by Dr. Claes Lundgren, professor of physiology at the State University of New York at Buffalo, and a Swedish company, nicotine gum has been shown to especially help heavily addicted smokers quit, said Bachman. "For lighter smokers, the behavioral techniques will be more relevant."

The behavior modification techniques help people overcome social and psychological reasons for smoking, while Nicorette fights the physical addiction, Bachman explained.

A group of about 10 smokers will meet for eight 90-minute therapy sessions, spaced over a month in declining frequency, he said. The therapy includes rapid smoking, relaxation training, and assertiveness training.

In the rapid smoking technique, Bachman said, patients are instructed to rapidly smoke three cigarettes of the brand they normally choose. They puff to the beat of a tape recorder voice that says, "Smoke. . .smoke. . .smoke," one command every 10 seconds.

"The natural way people smoke is usually one inhalation every 35 or 40 seconds," Bachman noted. "Rapid smoking is an unpleasant experience."

The rapid smoking is videotaped, with close-up views of uncomfortable smokers, and the tape is replayed for the group. "Later, people can recall the scene to combat their urge for a cigarette," Bachman explained.

It should be mentioned, Bachman said, that rapid smoking and nicotine gum are not safe for people with certain specific medical conditions. Also, women who are or may become pregnant, or who are nursing, should not use these techniques (nor should they smoke, he noted).

Their physicians are required to review participants' medical records before they may enroll in the program. A behavioral medicine clinic physician will prescribe the gum for all enrolled patients.

After the first four sessions, Bachman said, relapse prevention skills are taught. Relaxation training gives people an alternative outlet for feelings of stress, boredom, anger, and anxiety—the major causes of relapse.

Assertiveness training helps smoke quitters deal with indirect social pressures to smoke. "Participants practice socially appropriate assertive responses such as, 'No, thank you. I choose not to smoke now.' "

Bachman pointed out that recent social and legislative changes have made it most often socially appropriate *not* to smoke, and that this will "undoubtedly reduce the relapse rate even more."

He said patients who relapse within six months after completing the program will be offered a renewed prescription for Nicorette and then, if necessary, repeat participation.

"By the end of the four-week program," Bachman said, "we expect most patients will have stopped smoking and possibly even chewing the gum," the use of which should steadily decline, an upper limit being 30 pieces a day.

Also, he added that "the type of person who wants someone else to do the work for him won't succeed in this program." Who will benefit are those who want help to help themselves.

He conceded the approach is still a "secondary attempt, a treatment technique versus a primary prevention technique on a national level, which would be the ideal."

Bachman will supervise the new program, and therapy sessions will be conducted by psychologist Fritz Bottjer. There is a fee. For information call (415) 497-5869.

FOR IMMEDIATE RELEASE

SHORT-ACTING SLEEPING PILLS ARE ANTIDOTE TO JET-LAG, STANFORD RESEARCHERS SAY

STANFORD—

Judicious use of short-acting sleeping pills is an effective treatment for jet-lag, but taking long-acting sleep drugs can make jet-lag symptoms worse, report sleep researchers from Stanford University School of Medicine and Henry Ford Hospital in Detroit.

A new study published in the June 15 issue of *Science* magazine shows that short-acting sleeping pills can completely reverse nighttime insomnia and daytime sluggishness associated with jet-lag or other sudden and major disruptions of the sleep-wake schedule.

In contrast, long-acting sleeping pills that continue to act after the night is over, increase the daytime drowsiness that typically follows a sudden sleep cycle disruption, the scientists reported.

The research demonstrates that a full eight-hour period of sleep is capable of overriding the body's natural sleep-wake cycle, and can restore alertness in a person forced to be awake when he would normally be in bed, the scientists said.

The researchers also found that, if untreated, sleep patterns and daytime function can be disturbed for at least three days following a 12-hour shift in bedtime, the researchers said.

The findings could be significant for thousands of travelers who cross multiple time zones, and for thousands of employees who work on rotating shifts, said Wesley Seidel, a researcher in the Stanford Sleep Research Center and an author of the report.

"For people who know they must adapt to a change in sleep-wake schedule—such as a businessman who flies to Japan and must be awake the next day during an important meeting—careful use of certain sleeping medications could be a solution," said Seidel.

He cautioned that only short-acting drugs would be recommended for use in these circumstances. "A short-acting sleeping drug wears off within eight hours," he noted, "while the effects of long-acting medications continue well into the waking period of the next day, actually increasing daytime drowsiness and impairing performance in certain mental tasks."

Seidel carried out the research with Dr. William Dement, professor of psychiatry and behavioral sciences, and director of the Sleep Research Center at Stanford Medical School. Their colleagues at the Sleep Disorders and Research Center at Henry Ford Hospital in Detroit are Thomas Roth, Timothy Roehrs and Frank Zorick.

-more-

6-8-84

The work was supported by grants from the National Institutes of Mental Health and by the Upjohn Company, which also provided the medications.

The study was performed on 24 young, healthy volunteers with normal sleep patterns. After two nights of going to sleep at midnight and waking at 8 a.m., the volunteers were allowed to sleep from midnight only to 2 a.m. and then shifted to a noon bedtime for the next three days.

Before retiring at the new bedtime, eight subjects were given triazolam, a short-acting sleeping medication, eight received flurazepam, a long-acting sleeping agent, and the remaining volunteers were given an inert placebo pill.

Length and depth of sleep were monitored, and the volunteers' waking alertness and mental function were measured—with visual-tracking, card-sorting, and copying tasks—during the waking periods after each eight-hour repose.

Those volunteers given the short-acting sleeping pill slept longer during the night than the others. They also were more alert and performed better when awake than those who took no medication and those who took the long-acting sleeping drug, Seidel said.

Although volunteers who took the long-acting flurazepam were able to sleep while in bed, they were also the most severely impaired in their daytime activities, Seidel said.

Those who took the placebo slept fitfully but functioned better while awake than flurazepam subjects, Seidel said. However, their alertness still did not reach the levels of those who had received the short-acting triazolam drug.

"The behavior of the placebo group confirms that sleep and subsequent alertness are significantly impaired for at least three days after a sudden 12-hour shift of the sleep-wake schedule," the researchers wrote.

"In terms of waking alertness and performance, triazolam is preferable to flurazepam in the treatment of transient insomnia associated with a sudden sleep schedule changes such as occurs in trans-meridian travel and shift-work rotation," they concluded.

FOR IMMEDIATE RELEASE

STANFORD DEPARTMENT CHAIRMAN RESIGNS AFTER ACADEMIC INVESTIGATION

STANFORD—

Dr. Kenneth L. Melmon, 49, has voluntarily resigned as chairman of the Department of Medicine, effective July 31, after a committee of the Stanford University School of Medicine said he was guilty of "grossly negligent scholarship," the University announced Thursday, June 7.

But the committee said that no fraud had been committed and Melmon had no conscious intent to deceive. Melmon will retain his faculty post. He has received a letter of censure from Stanford University President Donald Kennedy.

The faculty committee investigated charges that Melmon had used unattributed copyrighted material from Goodman and Gilman's, *The Pharmacological Basis of Therapeutics*, a book he helped edit, into a chapter he wrote for Williams' *Textbook of Endocrinology*. Both books are considered standard biomedical texts.

Kennedy wrote Melmon June 6:

"I agree with the findings and conclude that academic fraud has not been committed. I also agree with the committee that your unpermitted, unacknowledged and extensive use of material (about 24 percent of your chapter) from the Goodman and Gilman textbook in Chapter 10 of the *Textbook of Endocrinology* represents professional misconduct, in the sense of grossly negligent scholarship, for which you must be held accountable. By this letter, I am censuring you for your conduct."

In the letter, Kennedy also stated, "In light of your resignation (as chairman), I do not believe any action beyond this letter of censure is appropriate.

"I know that you recognize your conduct was a serious departure from the high standards of scholarship required by the university—standards to which you personally have always been committed."

Melmon said he was resigning because "the mistake was a serious one for me to have made. Given my commitment to high standards of scholarship at the university, and the public perceptions that might result from my continuing to serve as chairman, I ask that you accept this decision.

"The vast majority of my colleagues at Stanford and elsewhere, who have spoken out, deeply feel the ultimate result of my resignation as chairman in addition to a censure has been more than sufficient response to my mistake."

In a joint statement Kennedy, Vice President for Medical Affairs Lawrence Crowley, and Medical School Dean Dominick Purpura said: "We have accepted his voluntary resignation with thanks for his past service as chairman, and for his sensitivity and devotion to the university's interest."

In his censure letter Kennedy wrote:

"The borrowing for publication from the work of others is a matter of considerable significance.

"(Your action) represents a degree of carelessness in dealing with the intellectual property of others that violates the fundamental norms of the academic profession."

However, Kennedy's letter also acknowledged mitigating circumstances cited by the committee, including Melmon's move from the University of California at San Francisco to Stanford at the time he was working on both textbooks, his heavy departmental responsibilities and pressures and his reliance on assurances of editors that the matter of permissions "had been taken care of."

A clinical pharmacologist, Melmon holds the Bloomfield endowed chair in the Department of Medicine and has a joint appointment in the Department of Pharmacology.

The Medical School's Committee on Ethical Scientific Performance, which investigated Melmon and submitted its unanimous recommendations to Kennedy, concluded:

"It is manifest, and undisputed, that Chapter 10 (Melmon's) as it appears in print is seriously out of conformity with professional standards in the unpermitted and unacknowledged use of the work of others.

"Dr. Melmon had no conscious intent to deceive," but his efforts regarding both permission and attribution "were grossly inadequate."

Melmon was an associate editor of the sixth edition of the Goodman and Gilman book, published by Macmillan in 1980, and he wrote a chapter in the sixth edition of the Williams' text which was published in 1981 by W. B. Saunders. The latter book includes contributions of 49 authors and Melmon had written chapters for earlier editions of the same work, all of which contained appropriate attributions.

Passages taken from nine chapters of Goodman and Gilman, written by four different authors, were incorporated into Melmon's 73-page chapter of the Williams' book. But according to the committee, Melmon's chapter "as it appeared does not contain any acknowledgment of the extensive use of the Goodman and Gilman material, nor are the excerpts identified by quotation marks, indentation, or other means."

Last March in public statements while the investigation was in progress, Melmon freely acknowledged through his attorney, Stanford Law Professor Jack Friedenthal, that he had used materials from Goodman and Gilman "nearly verbatim with some minor editing for style." But he insisted he had always intended to use them only with permission and attribution.

Melmon, according to this reconstruction of events, had been asked by Williams to include more pharmacological details to the chapter from the rough-typed manuscripts of the forthcoming sixth edition of the Goodman and Gilman book.

Melmon had told Williams he was not interested in doing this, but Williams insisted. Melmon then agreed to incorporate the material only if Williams himself obtained permission from Goodman and Gilman.

Williams died while the editing of the Textbook of Endocrinology was in progress. And four years later, after both books had since been published, Melmon was informed by an editor of Goodman and Gilman that permission had never been sought or given.

"The basic facts are not in dispute," the committee said. "The committee's subsequent investigations and deliberations have gone to the questions of whether Dr. Melmon in fact intended that the chapter appear as it does, with neither permission nor acknowledgment, and if not, whether the steps he took to see that permission and acknowledgment were made were reasonable."

The committee could find no direct confirmation of the arrangement with Dr. Williams to secure permission. Dr. Melmon's communications with him were oral . . . Dr. Williams' papers have been destroyed since his death."

According to the committee, Melmon had said that because he was overcommitted he had not reviewed the final galleys or the published chapter in the Williams' text except for a cursory review of the first set. This has been disputed by an editor at Saunders.

However, the committee said there was no evidence that these exchanges constituted "an intent to cover-up the facts of the matter. Nonetheless, the material is troubling and suggests the possibility of a higher degree of recklessness in dealing with the intellectual property of others," the committee said.

"Dr. Melmon, as an editor of Goodman and Gilman, had privileged access to the unpublished Goodman and Gilman manuscripts and therefore a special responsibility to the authors.

"Dr. Melmon was responsible for assuring that permission for use of the Goodman and Gilman material was obtained.

"Dr. Melmon was responsible for assuring that proper attribution was incorporated into Chapter 10.

"Dr. Melmon's failure to carry out his responsibilities resulted in the unpermitted and unacknowledged use of a very substantial amount of material from Goodman and Gilman."

A graduate of Stanford and the University of Calfifornia Medical School in San Francisco, Melmon is a member of the Institute of Medicine of the National Academy of Science.

Committee members included Dean Purpura, chairman, and Prof. Jack D. Barchas, and Roland D. Ciaranello, psychiatry and behavioral sciences; John A. Collins, surgery; Stanley Falkow, medical microbiology, and David Korn, pathology. Prof. Ernest R. Hilgard, psychology; and James P. Collman, chemistry, were added to the medical school's standing Committee on Ethical Scientific Performance.

—30— mg3

Following is a June 6 statement of Melmon.

The period during the investigation has been a most difficult one for me. Although there have been numerous hearings, investigations and inquiries, the ultimate findings of the investigating committee and the university president confirm the facts as I stated them from the outset: I made an error, albeit a serious one, but an unintended error.

The ultimate result of the inquiry was inevitable from the outset. The process was directed toward a committee report that could only find what I had admitted—a serious error. Having so stated, the committee, which had worked so hard and met so often, could not simply stop with a single paragraph. It therefore gave in detail whatever evidence it had available to confirm what it found. Thus the report, in its factual section, was unbalanced—providing no details of evidence favorable to me although, from time to time, admitting such evidence exists. Much of the report was prepared by univerity attorneys who not only advised the committee but the president as well.

Although the report was, as I was led to believe, not to be a formal recommendation but an informal analysis, it has by the university president's own terms, formed the major basis for his conclusions and is now being circulated despite the fact that it was not prepared to be a comprehensive or balanced document but an in-house working paper.

As a result of the crushing pressures of the process, I realized that I had to resign as department chairman rather than allow the affair to blow up into a giant confrontation among my friends and colleagues that would inevitable weaken or destroy the work that I have done over the past five years.

I and the vast majority of my colleagues, both at Stanford and elsewhere who have spoken out, deeply feel that the ultimate result of my resignation as chairman in addition to a censure has been more than sufficient response to my mistake. No evil precedent was set by my action for there was no fraud or intention.

6-7-84 —30—

Following is a June 3 letter from Dr. Kenneth L. Melmon, professor and chairman of the Stanford Department of Medicine, to President Donald Kennedy.

The purpose of this letter is to tender my resignation as chairman of the Department of Medicine.

While you and the committee concur that my error in not assuring adequate editorial control of some of the material I published in Williams' textbook does not reflect fraud or fraudulent intent, I feel, nevertheless, that the mistake is a serious one for me to have made.

Given my commitment to high standards of scholarship at the University, and the public perceptions that might result from my continuing to serve as chairman, I ask that you accept this decision.

I would like to discuss with you at our meeting on June 4 the steps that might be taken to minimize any adverse effects of this resignation on the department and on the School of Medicine and to accomplish an orderly transition of leadership for the department.

6-7-84 —30— Rep. 6a Melmon1

Following is a June 6 letter to Melmon from Kennedy ruling on the report of the Committee on Ethical Scientific Performance.

I have read carefully the report of the Committee on Ethical Scientific Performance on the matter involving you and attentively considered the memoranda submitted in your behalf as well as your own statements. On the basis of its thorough analysis of the circumstances, the committee found that fraudulent intent was not established and that you had no conscious intent to deceive; I agree with these findings and conclude that academic fraud has not been committed.

On the other hand, I also agree with the committee that your unpermitted, unacknowledged and extensive use of material (about 24 percent of your chapter) from the Goodman and Gilman textbook in Chapter 10 of the *Textbook of Endocrinology* represents professional misconduct, in the sense of grossly negligent scholarship, for which you must be held accountable. By this letter, I am censuring you for your conduct.

The committee considered mitigating circumstances, including your move from UC-San Francisco to Stanford, your heavy departmental responsibilities, and other pressures. I am sympathetic with these circumstances. Indeed, the entire system of academic clinical medicine in this country may have evolved to a point at which extraordinary pressure is producing extraordinary behaviors at much too high a rate.

Professors and chairmen of medicine, like other clinical academicians, are expected to run large research programs and to produce large numbers of scientific papers each year—and also to maintain a full set of clinical, administrative, and teaching responsibilities. Nevertheless, the existence of such pressures—however exigent they may be—cannot become an excuse for personal failure to fulfill the responsibilities of the scholar. The borrowing for publication from the work of others is a matter of considerable significance. Your inadequate effort to assure appropriate acknowledgment of other authors' work (taking the telephone assurances of Dr. Williams that the matter "had been taken care of" as guarantee of the permission), your intermittent efforts to have others confirm it during the editorial process, and your failure to examine the galleys carefully enough to ascertain whether your use had been acknowledged, represents a degree of carelessness in dealing with the intellectual property of others that violates the fundamental norms of the academic profession.

From our conversations, from your statements throughout the investigation, and from your letter of resignation as chairman of the Department of Medicine, I know that your recognize that your conduct was a serious departure from the high standards of scholarship required by the University—standards to which you personally have always been committed.

I want you to know that I appreciate your service and achievements as chairman and the devotion to the University's interests that led you to resign that office; and in light of your resignation, I do not believe any action beyond this letter of censure is appropriate.

VOLUNTEERS NEEDED FOR DIABETES-RELATED STUDIES

STANFORD—

Volunteers are needed to participate in new and ongoing studies at the clinical research center (CRC) of Stanford University Medical Center.

The studies, under the direction of Dr. Gerald Reaven, professor of medicine, are designed to increase understanding of how the body absorbs and uses glucose, insulin and dietary fats.

New projects focus on such factors as carbohydrate intake, weight loss, and cholesterol.

Volunteers should be free of major illnesses other than diabetes. Non-diabetic volunteers are also sought.

All studies are conducted at the CRC. They vary in duration from two days to a month. Depending on the project, procedures may include blood sampling, overnight hospitalization, and meals aimed to test dietary effects.

Volunteers also receive complete physical examinations, including laboratory evaluation, free of charge.

Interested volunteers should call (415) 497-5430 between 9 a.m. and 4:30 p.m. weekdays, for further information. Ask for Ann Coulston or Clarie Hollenbeck.

NEW SHARED FACILITY HELPS SCIENTISTS SCREEN CELLS

STANFORD—

A new high technology research facility at Stanford University School of Medicine is helping scientists get a closer look at many different cell types in the body.

The new facility, shared by a variety of users, contains ultramodern cell-sorting equipment capable of scanning 5,000 cells per second and singling out one specific cell from a sea of millions.

Diagnosing leukemias, figuring out how the immune system works, learning how drug resistance develops, revealing the genetic basis for muscular dystrophy, and understanding how genes are regulated, are just a sampling of areas where cell-sorting is providing new insights.

An outgrowth of the laboratory of Dr. Leonard Herzenberg, genetics professor, the shared facility was recently established with a grant from the National Institutes of Health and gifts from Becton-Dickinson, Inc.. Space has been allotted for the facility by medical school dean Dominick P. Purpura, in the medical center's third floor science wing.

The facility consists of two fluorescence-activated cell sorters (FACS), one FACS analyzer, and a computer specially programmed to collect, store, retrieve, and analyze data from the FACS equipment.

Dr. David Parks, research associate in the department of genetics, directs the facility. Dr. Patricia Jones, associate professor of biological sciences, chairs the facility's users committee.

Although the FACS machine is not new—it was developed by Herzenberg and colleagues in the late 1960s and early 1970s and is now manufactured and sold by Becton-Dickinson—the expense of the machines has limited their widespread use. The new shared facility makes the equipment available to a wide spectrum of users at Stanford, Herzenberg said.

"It is similar to any other large, expensive research facility such as an NMR (nuclear magnetic resonance) center or a linear accelerator," Herzenberg pointed out. The resource can be shared by many groups working on diverse projects.

6-6-84

-more-

In addition to his own laboratory which focuses on understanding the different types of lymphocytes involved in the immune system, research groups from the biology department as well as other medical school departments are currently makimg frequent use of the machines, said Herzenberg.

These include the labs of Robert Schimke, who is studying how cells develop resistance to drugs, Irving Weissman, Patricia Jones, Gary Fathman, and Eugene Butcher, who are studying the immune system, and Helen Blau whose focus is muscular dystrophy, Herzenberg said.

"The potential applications of the cell sorting technique range over virtually all biology and medicine," Herzenberg explained.

The machine identifies and isolates cells by means of the specific molecules that coat cell surfaces.

For example, suppose a researcher wants to separate out for study a specific type of cell from the immune system. A fluorescent-tagged monoclonal antibody is produced that attaches only to the molecules coating that cell type's surface. This fluorescent "flag," added to a mixture of cells, binds to and identifies the cells of interest. The FACS machine then physically removes the flagged cells from the mixture found in the biological sample.

Liquid containing the cells flows through a laser beam, and then breaks into droplets usually containing a single cell. The dye-flagged cells fluoresce when hit by the laser light, and this fluorescence, when sensed, triggers an electrical charge to be applied to the droplet stream. The electric field flicks charged droplets containing fluorescing cells out of the main stream into separate collecting dishes.

This tool is extremely powerful in its ability to sift through and sort cells, Herzenberg said. It can screen up to 5,000 cells per second and it can sort one fluorescing cell in millions of unmarked ones. In addition, new dyes and new models of the cell sorter incorporating more than one laser, make it possible to identify subsets of cells marked by two or more different fluorescent tags.

Another major improvement for those working at the shared FACS facility is a new piece of software, developed by Wayne Moore in Herzenberg's lab for a dedicated Digital Equipment Corporation VAX computer.

The "Electric Desk" program automates the process of collecting, storing, and analyzing data during runs on the machine. The software will be copyrighted through the university, Herzenberg said, and made available to other FACS laboratories around the world.

STANFORD SCIENTISTS STUDY PROTEINS INVOLVED IN CELL MOVEMENT

STANFORD—

A Stanford scientist and his colleagues have viewed for the first time the repetitive interactions of the protein cogs and gears that help living things move.

The work focuses on proteins responsible for movement in living things throughout the biological world.

Like cogs pushing against gears, these protein molecules move against each other. Their mechanical interaction is the basis for muscle contraction, cell migration, cell shape changes, and flow of cytoplasm and structures called organelles inside living cells.

The work was described Friday (June 1) by Dr. James Spudich, professor and chairman of Stanford Medical School's department of cell biology, and medical student Ronald Vale in the final presentation of the spring SMASH lecture series at Stanford University School of Medicine.

For over a decade, Spudich had searched for a test-tube mixture in which he could determine the essential molecular ingredients of locomotion.

Finally last year, Spudich and visiting University of Connecticut professor Dr. Michael Sheetz developed an elegant and simple solution for viewing the interaction of actin and myosin molecules, two important motility proteins.

Inside cells, actin molecules are strung together in long ropes. Movement occurs as myosin molecules ratchet their way along these ropes.

No one had actually observed myosin molecules pulling themselves along actin cables prior to Spudich's and Sheetz's achievement, because the tiny protein particles were too small to see through a light microscope.

The two scientists accomplished their feat by coating microscopic beads with thousands of myosin molecules spread in a thin layer. Under the microscope the myosin-coated beads could be viewed as they climbed the actin ropes by means of thousands of tiny grasping myosin "hands."

In their research, the scientists used actin cables which line the inner surface of cylindrical cells from a freshwater alga called *Nitella*. In a delicate operation, the researchers cut the cells lengthwise and laid them flat, exposing rows of many parallel three-centimeter-long actin tracks.

After placing a solution of myosin-coated beads on the cables, they looked in the microscope and saw the beads moving across the cell surface at exactly the rate predicted from studies of rates of contraction of intact muscles. When the scientists measured the velocity of spheres coated with a different type of myosin protein—found in a species of amoeba—the spheres moved at the amoeba's characteristic speed.

Cathy Berlot, a third-year medical student, and postdoctoral fellow Linda Griffith have shown that a specific chemical alteration of the myosin molecule that occurs naturally in amoeba cells also acts as an on-off switch for movement in the new test-tube system, Spudich said.

In another study, the researchers added an antibody that latched on to one end of the myosin molecule. The antibody stopped the spheres in their tracks, demonstrating that the antibody-bound end of the myosin molecule is essential for normal locomotion. This end of the molecule, said Spudich, probably grabs hold of actin, like a rope-climber's hand.

Now, Spudich and his associates plan to use genetic engineering techniques to find precisely which portions of the myosin molecule are crucial to the protein's function.

Arturo DeLozanne, a graduate student, is isolating from DNA the genes that code for the myosin protein. The researchers can then make specific changes in a gene to produce an altered myosin molecule, Spudich explained.

If the beads coated with the genetically tampered myosin move at a different rate from the norm, the scientists will suspect that they altered an important portion of the myosin molecule. This is a fine-tuned method for finding out how the myosin molecule works, Spudich explained.

In the last month, Spudich and first-year medical student Stephen Kron refined the technique further when they succeeded in laying down tracks of actin cables without resorting to *Nitella* cells. They spread a surface with chemical "hooks" engineered to latch onto actin cables and hold them in orderly arrays for the myosin-coated balls to roll along. This bed of actin provides a pure uncontaminated system for study, Spudich explained.

Vale is investigating the movement of organelles inside axons, the long impulse-carrying fibers of nerve cells. In collaboration with Sheetz and researchers at the Woods Hole Oceanographic Institute in Massachusetts, Vale hopes to determine the essential proteins involved in organelle movement inside giant axons from squid.

Some organelles found in squid axons ferry essential components to the tip of the axon from the main cell body, Vale explained. Using video-enhanced microscopy, Vale observes these tiny cellular structures attaching to and gliding along a network of filaments. Preliminary evidence suggests that the filaments are microtubules composed of a protein called "tubulin," he said. He has not yet identified the "filament-binding proteins" from the surface of the organelles.

There are as yet no clinical applications from this work, Spudich said, but the research could shed light on the molecular basis of certain muscular and neurological diseases, as well as abnormalities in the immune system where directed cell movement is critical. The research also might reveal new information about cell shape and division abnormalities seen in cancer, Spudich suggested.

The research was supported by the National Institutes of Health and by the American Heart Association.

DAY CARE OFFERS COMPROMISE FOR PSORIASIS PATIENTS

STANFORD—

Janet Schultze said she couldn't have entered the hospital the last time her psoriasis flared up even if she'd wanted to.

"That's because I have a special little person at home who needs me, my son Daniel," explained the 27-year-old who's experienced bouts with the skin disease for the past 10 years.

So last February Schultze spent 12 days at Stanford University Medical Center's psoriasis day care center (DCC), a 7:30 a.m.-3:30 p.m. program geared specifically for psoriasis patients with similarly vying obligations.

"Most day care patients would ideally be admitted to the hospital for at least some time," said Dr. Eugene Farber, professor and chairman of dermatology. But psoriasis, which affects up to six million Americans, poses a dilemma. Although it is a chronic disease requiring intensive therapy, it rarely confines one to bed, so patients find themselves with practical choices to make regarding their treatment.

The DCC evolved about 15 years ago as a compromise solution, Farber said. Located in the Hoover Pavilion at Stanford Hospital, it serves about 10-15 patients at a time.

Referred by the Stanford dermatology clinic and private physicians, patients are examined and put on individual regimens, usually consisting of anthralin (a hard paste applied to the lesions), tar baths, oil shampoos, and ultraviolet light treatments. Also, free time for relaxing and socializing is an important element of the program, Farber said.

At the end of the day medications are removed, allowing for another bath and sometimes an additional lamp treatment. Then patients are instructed to use topical treatments at home overnight. The condition may take from a few days to a month to clear up, Farber added.

"We can't cure psoriasis, but we can effectively treat it," said Dr. Elizabeth Abel, assistant professor of dermatology who runs the DCC and phototherapy unit. "In most cases it will come back, within months to a year." She added that fortunately, most health insurance companies do now cover costs of treatment in the day care program.

6-4-84

-more-

The basic cause of psoriasis is unknown, though doctors have pinpointed various triggering factors that may set off the disease in people genetically predisposed to it. These include injury to the skin, streptococcal infections (especially in children), sun sensitivity reactions, prolonged low humidity, certain medications, steroid withdrawal, or extreme stress.

Known to be a sort of cellular hyperproduction, psoriasis is a worldwide problem that comes in many forms and can begin at any age, hitting both sexes equally and often associated with arthritis.

The most common form of psoriasis is characterized by thick, red, scaling plaques over different parts of the body, sometimes including the scalp and the nails. Some patients suffer terribly from itching, Farber said.

But psoriasis is a very unpredictable disease, Abel noted. It may go away on its own and not reappear for years. Dispelling a common misconception, she added that psoriasis is not contagious.

This is an important point since, besides the obvious physical handicaps, psoriasis almost always presents psychosocial problems. "When something's wrong on your skin people always ask, 'What do you have? Can I catch it?' " explained Dr. Kira Flanzraich, dermatology resident.

One woman, Flanzraich recalled, had been told repeatedly that she wasn't the only one with the disease. "But she never believed it and always felt depressed. Now, at day care, she sees many other people with psoriasis, and this gives her a better perspective."

Every Wednesday for an hour DCC patients meet in group therapy with Dr. John Glathe, clinical associate professor of psychiatry. The groups are voluntary and free, said Farber.

"For me," said Schultze, "just being with other patients was very helpful. Most of them were considerably older, and this showed me that life goes on, and other things are more important—such as having a husband who understands and lends support.

"The nurses," she added, "were extremely informative, but easy going as well. There was no guilt trip of the type I'd encountered previously," with doctors who'd implied that she must have done something wrong for the condition to return.

"Our major aim is to educate patients so they're better able to manage their own psoriasis when they leave here," said Abel, adding that she hopes to include occupational therapy in the day care regimen in the near future.

In addition to the DCC, clinic, and hospital offerings, a weekly self-help group for psoriasis patients and family members has recently started at Stanford. "We're the first anywhere to offer this type of meeting as a supplement to regular clinical programs," Farber said.

Schultze, who attended the first four-week series, said that though she'd always thought she was "well-versed in psoriasis" before, now her knowledge had definitely been expanded.

OR DIRECTOR NAMED EMPLOYEE OF THE YEAR

Photos available on request.

STANFORD—

A nursing manager who had never even worked in an operating room before being chosen to lead it was named Stanford University Hospital's employee of the year at a banquet Wednesday night.

Claire Mailhot, who was appointed two years ago to the OR directorship for her management expertise, conceded after the 26th annual employee service awards banquet that even though "I didn't even know the language" when she was appointed, now "you name it, I've learned it."

The Thomas A. Gonda Employee of the Year Award, established in 1976, is named for the former hospital director who has been associated with Stanford Medical Center for 30 years, currently serving as professor and chairman of the department of psychiatry.

Mailhot, ninth recipient of the award, was introduced as having been a "great motivating force and role model" on all the units she's served since coming to Stanford Hospital as a staff nurse in 1972.

During that time Mailhot took over as clinical nursing coordinator of the acute gastrointestinal unit, of the recovery room, and then as OR director.

"A good part of my management style," she explained in an interview, "is based on the fact that some of my own learning experiences were very painful. I don't believe in the sink-or-swim attitude. How can you be a caring professional and a good patient advocate if you're constantly whipped around and no one cares about you?"

More than 230 of 475 persons eligible for five, 10, 15, 20, 25 and 30 year awards for service showed up for the banquet at Hyatt Rickeys of Palo Alto to receive pins and accessories. Also honored for their contributions were all employees and retirees with 20 or more years of service.

Besides the Gonda Award for dedicated and exemplary service for Mailhot, an assistant director of nursing services, special awards went to five surprised "outstanding employees." They are: Elizabeth Griffith, telecommunications; JoAnn Hattner, dietetics; Randall Reeve, neonatal nursery; Heliodoro Villegas, housekeeping; and Mary Thompson, coagulation lab.

Donald Utt, associate director of the hospital, was given a special recognition award for 17 years of dedicated service. Utt plans to retire from his hospital position this summer.

Dr. Lawrence Crowley, vice president for medical affairs and president of the hospital, was among those presented with 20-year pins. In remarks to the crowd he noted that the banquet was "one of the biggest communication events of the year" in relaying gratitude to all the staff for functioning so well individually and as a team.

Daniel Robinson, director of personnel management and master of ceremonies for the event, noted that the high number of eligible five-year employees—more than 200 and close to double last year's group—reflects a low rate of staff turnover at the hospital.

COCAINE ABUSE REACHES EPIDEMIC PROPORTIONS, STANFORD PSYCHOLOGIST CONTENDS

STANFORD—

The Bay Area is in the midst of a severe cocaine epidemic, a Stanford psychologist contends.

Between 1980 and 1983, deaths related to cocaine use doubled, said Dr. Robin Press, a psychologist with the Stanford Alcohol Clinic.

"The mortality rate for cocaine may even exceed the mortality rate for heroin." Press said. "But these are 'soft' data" that are difficult to confirm because of multiple drug use, she added.

Nationally, 22 million people, or one out of 10 individuals report having used cocaine at least once, Press said. Every day 5,000 people try the substance for the first time, and one million individuals are dependent on the drug.

Press discussed use and abuse of cocaine Thursday May 31 at Stanford University Medical Center, in the last of four public lectures sponsored by the Alcohol Clinic.

Cocaine is a highly addictive drug, Press contended, although users' symptoms do not fit the traditional profile for addiction.

"The classical definition of addiction may have to be revamped," Press suggested, to include compulsion, loss of control, and continued use of a substance despite adverse consequences.

Although habitual cocaine users do not display physical dependency and physical withdrawal symptoms, the traditional hallmarks of addictive drug use, these individuals may seek out the drug while their lives fall in ruin about them, Press said.

Career, personal relationships, and finances of a cocaine addict may all be destroyed while the person pursues the habit, Press said. "Their lives focus solely on the drug. That takes precedence over everything else," she said.

Press cited several examples, including one young man who used up an entire $400,000 inheritance in one year to support his cocaine habit, while his sister spent an inheritance worth $120,000.

"That shows the sort of compulsion and disregard for other things" that characterizes cocaine addicts, Press said.

Studies of animals show the power of cocaine. Monkeys will self-administer doses of the substance at a rate of up to 60 doses per minute, Press said. They will choose it over food, water or sex, even to starvation, exhaustion, or death, she added.

Some animals will press a bar over 12,000 times to receive a single dose, and they choose high doses of cocaine administered simultaneously with an electric shock rather than lower doses of the drug, she said.

But despite an initial pleasurable rush from cocaine, "it is a mystery why people continue to use the drug even when unpleasant effects begin to take over," Press noted. People and animals will go back to the drug even after they have experienced convulsions from its use, she said.

6-1-84

-more-

In addition to convulsions or seizures, anxiety, depression, insomnia, loss of appetite, loss of sexual drive, hallucinations, paranoia, psychotic behavior and even suicidal tendencies replace the initial high as cocaine use continues over a period of time, Press added.

Other long-term effects include tremors, weight loss, chest pains, blurred vision, nausea, and mucous membrane damage at the site of application.

Cocaine acts at two sites in the body, Press said. It is a local anesthetic that acts peripherally at the site of administration, and it is a central nervous system stimulant that depresses the action of inhibitory pathways in the brain.

There is no direct evidence demonstrating that cocaine use causes brain damage, Press said, although certain behavioral abilities decline with continued use.

Press has studied cocaine users' abilities to perform tasks involving memory and attention. Memory deficits are most striking in those who "freebase" or smoke cocaine. They are not so clear-cut in those who "snort" the drug, she said.

But "I wouldn't rule it out," Press added. It may take several years of frequent use for such problems to show up, she suggested.

Out of every 100 people who try cocaine, 30 will abuse it at some time, Press said. But there is no typical personality profile of a likely cocaine abuser, she noted. "The picture of the affluent, powerful, successful, energetic, entrepreneurial type may be more due to the economics involved than anything else," she said.

But cocaine is no longer solely a drug of the rich, Press said, although there is a joke going around in the substance-abuse community that says "cocaine is God's way of telling you when you have too much money."

Cocaine addiction and abuse must be treated similarly to alcoholism, said Press, who has run cocaine user group therapy sessions. Often a short hospital stay is required followed by continued outpatient therapy. There are organizations available to help, including Cocaine Anonymous and a cocaine hotline (800-COCAINE), she observed.

The first step in kicking the habit is admitting that there is a problem. Once drug-free, the major difficulty is in maintaining the "clean" lifestyle, Press said.

"The drug will always be available," she noted, so recovered cocaine addicts must develop internal controls and ways of coping that enable them to refuse the temptation.

Every recovered addict would like to hear that, once the habit is kicked, they can safely go back to using cocaine occasionally once a week, Press said.

"But the sad news is that there is no possibility of a return to controlled usage once addiction develops," she concluded.

BLOOD CENTER SCHEDULED OPEN HOUSE AUG. 3

STANFORD—

The Stanford University Blood Center is holding an open house from 3 to 6 p.m. Friday Aug. 3 to acquaint the public with its new facilities.

The Blood Center, which provides an estimated 18,000 units of blood to the community annually, was relocated to expanded facilities in the same building, 800 Welch Road, where it has been for three years.

Maureen Roskoph, supervisor of volunteers, said the open house will include refreshments and tours of the expanded facility, including laboratories where blood is processed after collection.

Roskoph said the expansion, which enables more persons to give blood simultaneously, should reduce or eliminate potential waiting or delays by donors. Additional laboratories have been installed in the building to increase research efforts involving blood, she said.

Roskoph said no blood will be drawn during the three hour reception. However, she added the center will be open to donors from 8:30 a.m. to 3 p.m. on Aug. 3.

DONOR CRISIS AVERTED, BLOOD CENTER SAYS

STANFORD—

Public response to a a blood recruitment drive have returned supplies at Stanford Blood Center to normal, annnouced Dr. Edgar Engleman, medical director.

"We had a super response," Engleman said this week. A week earlier he had warned a critical shortage of blood could have resulted in patients doing without needed transfusions.

Rhoda Burns, supervisor of blood donor recruitment, said 418 persons had given blood during the week ending July 21, about twice the 200 donations expected on a typical week during the summer.

"We just want to thank everyone who responded. Some people really ended up waiting a long time, and they deserve a special thanks for their patience," Burns said.

She added that supplies by July 23 were above the 240 unit reserve needed to be on hand to protect against emergencies.

While the crisis has been resolved, Burns emphasized the need for continued participation by the public to avoid a recurrence of last week's critical shortage.

Engleman, an associate professor of pathology and medicine, said the shortage affected California and perhaps the entire nation and was due to a number of causes, including a normal summer lull and economic factors increasing elective surgeries.

IMPLANTED DEVICE ASSAULTS COMMON FORM OF DEAFNESS

STANFORD—

Stanford researchers have begun clinical trials with multichannel cochlear implants—medicine's latest assault on a kind of deafness that afflicts an estimated 200,000 Americans.

Dr. F. Blair Simmons, professor of otolaryngology, has implanted two of the eight-channel devices, and a third patient will receive one this fall.

Though single-channel cochlear implants were first used in the 1960s, the technology has steadily improved. Stanford is one of three U.S. centers approved for testing of multiple-electrode implants.

The Stanford model—designed by Simmons and associates in the medical center and department of electrical engineering—consists of a cable of eight electrodes, which is threaded into the cochlea (an inner-ear structure vital to hearing) and connected to a receiver passing through skin and bone behind the ear. Sounds picked up by a microphone resembling a tie clip are converted to electrical pulses by a processor the size of a cigarette box, worn in a pocket or under clothing. The pulses travel up a wire to the receiver, which is connected to one of the cochlear electrodes. In turn, the electrode transmits pulses to the brain via the auditory nerves. The result: hearing.

"All I can say is it's the difference between hearing and not hearing," said Amy Sullivan, 68, one of Stanford's multichannel implant patients. Deaf for more than 40 years, Sullivan has rejoined the world of a grandchild's voice, a honking truck, a waiter reciting specials of the day.

Pending Food and Drug Administration approval of multiple electrode use, only one of the eight electrodes is hooked to Sullivan's processor (made by a Princeton, N.J. company, Biostim, and dubbed "Bioear"). Simmons has four patients wearing single-electrode implants.

Simmons cautioned that wearers cannot hear normally, but the implant helps in several ways.

"First, some deaf people can't modulate their own voices and end up speaking too loud or soft and maybe atonal, flat," he said. "This is a definite help for them.

"Second, it's nice to know the car behind you is honking or a semi truck is about to pass you or the dog wants out," he said. "Also, it's more fun to be in a sound environment."

Finally, for most deaf people, the implant aids lip reading.

"This is the big one," Simmons said. "For one thing they're aware people are talking at them and turn to face them. And the ability to lip read improves, especially with strangers."

The implants are medicine's attempt to substitute wire for the 30,000 hair cells—each sensitive to a different range of sound—that normally line the snail-shaped cochlea and convert sound transmitted from the middle ear to electrical pulses, passing them on to the auditory nerves and brain. When the cochlea fails—from infection, drug toxicity, or other causes—"sensorineural" deafness results.

In true "neural" deafness, Simmons explained, the auditory nerves fail and the crucial link to the brain is cut. Even a cochlear implant is useless. The implant also is of no use to people with "conductive" deafness, whose damaged outer or middle ears prevent sound waves from reaching the cochleas. Conventional hearing aids often are helpful.

The greatest challenge facing researchers, Simmons said, is how to process the many frequencies of sound to yield something like normal hearing. There are several theories.

"One is dump it all in and let the brain worry about it," he said. "That's the one-electrode approach. It works amazingly well, but it's not perfect.

"Then there's the pre-processing-necessary school of thought. That's us. You're not going to be able to duplicate the normal ear. You can't put 30,000 wires in." But sound can be chopped—or coded—into frequency segments, each of which will be carried by a different electrode, he said.

So far, no sound heard by wearers—even in laboratory tests using all eight electrodes—is exactly what it would be to a normal ear.

Simmons said low-frequency sounds, like a dog's bark or a knock at the door, are relatively easy to code. High frequency sounds, like human voices, are another story. Sullivan noted that sounds like running water or her car starting are much like she remembers them. An airplane-like sound turned out to be the lawn mower. But voices sound electronic.

"You have to get used to it," she said. "It's a metallic sound. It doesn't sound like a voice, but the words come through."

"It's like somebody talking under water," said Linda Jansen, the other Stanford wearer of the multichannel device.

Jansen, 36, lost her hearing two years ago. After receiving her implant, she wore the Bioear on her first day back at work as a computer operator at Signetics Corporation in Sunnyvale.

"The phone ringing sounded like somebody talking," she said. "When I went home that night and was deep-frying shrimp, my shrimp talked!"

Jansen, who seldom wears her microphone and Bioear, said she is more frustrated than helped by sound from the single channel.

"Everything sounds the same," she said.

Before the implant is in place, the range a given person will hear cannot be predicted, Simmons said, and laboratory tests show that hearing improves as a patient gains experience with the implant.

Sometimes background noise irritates. One wearer, a Montana rancher, complained of too much rustling and squeaking from his clothes and saddle. His Bioear was adjusted. Other patients, like a bulldozer operator who unplugs his hearing while working, appreciate the option of silence.

Despite possible benefits, volunteers for implants are rare, Simmons said.

"Deaf pride is an incredible obstacle," he said. "People who have been deaf a long time have made adjustments. The people we see here have chosen to stay in the hearing world."

Or they hope knowledge gained through their participation will help others. Jansen's two-year-old neighbor, Karen, also is deaf.

"If this can help her and kids like her, it's worth doing," Jansen said.

As in any surgical procedure, complications can arise. Sullivan has partial facial paralysis resulting when a nerve was injured during the operation. As the nerve heals, the paralysis is improving, she said.

Sullivan doesn't hesitate to recommend the implant to others with sensorineural deafness.

"It's wonderful to be able to hear again after not hearing so many years," she said. "For conversation, oh boy, there's no comparison. I was tense all the time, and in a group I was helpless. Now I don't miss much."

Jansen is less enthusiastic about the current state of the art but said she has high hopes for the multichannel approach.

"This may not help me, but it may benefit your grandchildren or mine," she said.

CLINICAL SCHOLAR DEVISES DIABETES COMPUTER GAME

STANFORD—

Dr. Bettina McAdoo, a Stanford participant in the Clinical Scholars Training Program, hopes her new computer game will prove useful in helping diabetic children gain knowledge and confidence in managing their illness.

McAdoo, through participation in the program, developed "Diabetes Adventure," the game she's now testing as a possible supplementary therapy to traditional medical treatment for diabetic children ages 9-14.

"Studies have shown that children have many psychosocial challenges and problems when faced with chronic disease. To help them adjust to the demands of the illness, health education should focus on practical, everyday concerns as well as physiological factors," McAdoo, a pediatrician, believes.

Her comments reflect a concern addressed by the Clinical Scholars Training Program, a two-year fellowship program funded by the Robert Wood Johnson Foundation of Princeton, N.J., which permits young physicians like McAdoo to develop skills in non-biological disciplines pertinent to the improvement of health care.

Since 1974, the program has trained about 50 clinical physicians seeking broader training related to the organization of health services, improvement of medical practice, and public policy in health, said Dr. Halsted Holman, professor of medicine and director of the Stanford portion of the program. (The program here is run jointly by Stanford, UCSF, and UC Berkeley. Currently, seven Clinical Scholars training programs are funded by the Foundation across the nation.)

"Introducing non-biological disciplines into medical thinking and practice will not by itself resolve the problems of health care," Holman said. "Nonetheless, these disciplines provide understanding and methods which are essential to the search for better solutions."

In the colorful, graphic computerized game McAdoo brainstormed, the player is cast under a spell. In order to break the spell he or she must retrieve a golden balance which has been stolen from the wizard and taken to a castle. While hunting down the castle, the player encounters—Wizard of Oz-style—a variety of barriers to overcome.

There may be a moat to cross, for example, and the knowledge that such vigorous exercise in a diabetic would awaken the "hypoglycemia witch." Multiple choices provide optional solutions: ride an alligator; take insulin; eat a sugar cube; cry.

A child sitting alone at a computer terminal, confronted with wizards, castles and obstacles, McAdoo reasons, can learn to make practical decisions while having fun, building a sense of independence, and remaining in control.

In pilot testing with diabetic and non-diabetic children, McAdoo found they'd learned a lot from their mistakes. They also learned that all situations were remediable.

"Playing the game has helped my daughter a lot," said Susan Holt of San Jose. "It kind of turns something that has a lot of negatives into something with a few positives," she added. Her daughter Melissa, 10, an outpatient at Children's Hospital at Stanford, was diagnosed with diabetes at the age of 6 and has since been featured in a movie on the topic as well as familiarizing herself with computer terminals.

"Diabetic kids are always being asked to join programs or attend groups related to their condition," explained Beth Bower, one of McAdoo's three research assistants, and a recent graduate of Stanford University's human biology department. "When one mother told her son about this project, his first reaction was: 'Oh, no, not another diabetic kids' thing.' But when he heard it involved computers, his eyes lit up."

Apparently McAdoo has capitalized on a modern type of child's play which is especially attractive these days, Bower suggested. And she's put into action the theory that children can and do learn while they may think—or look like—they're "just" playing.

McAdoo is now completing a more advanced level program for children who've mastered the first.

She sees the computer teaching tool as something a child might profit from while waiting to see the doctor, for instance, and as a system that would be fairly simple to distribute for wide usage.

"It's such an isolating and awful feeling when you find out your child is diabetic," said Holt. "It was the first time in Melissa's life that I felt, as her mother, I couldn't fix something. But the supportive medical care we've received, including things like this computer game, has helped enormously."

McAdoo's project has been supported by private foundations and industry. Johnson and Johnson Baby Products is funding the study effective July 1984 for one year, renewable upon review, she said.

McAdoo conceived her idea, she said, when she started in the Clinical Scholars Training Program at Stanford University Medical Center. A Stanford medical alumna ('78) who also has a master's degree from Stanford's School of Education, she worked with Picodyne, an educational computer software company, to develop the game.

"I didn't have extensive training in computers, and I wanted to learn," McAdoo said. Participating in the Clinical Scholars Training Program afforded her flexibility to pursue her new interests while broadening her medical education.

Postdoctoral fellows in the program attend seminars in such subjects as information sciences, health economics and policy, ethics, law, epidemiology, sociology, cost-benefit analysis, anthropology, and systems analysis to lay the groundwork for research with faculty advisors.

Projects have included such topics as: the character of health information in popular media; the relationship of mental testing results to daily living performance by the institutionalized elderly; sources of childhood accidents and parental responses to prevention programs; and psychological responses to chronic arthritis.

PURPURA APPOINTED DEAN OF ALBERT EINSTEIN COLLEGE OF MEDICINE

STANFORD—

Dr. Dominick P. Purpura has been appointed Dean of Albert Einstein College of Medicine, effective September 1, President Norman Lamm of Yeshiva University announced in New York Wednesday, July 25.

In assuming the deanship at Albert Einstein College of Medicine, the noted neuroscientist and currently dean at Stanford University School of Medicine returns to the institution he previously served from 1967 to 1981 in key academic research and administrative posts.

Last June Purpura, 57, had announced he would resign as dean of the Stanford University School of Medicine effective August 31, citing his desire to return to research and teaching. Purpura, however, would have continued to direct the development of new academic programs of the Stanford Medical School as an associate vice president for research.

In explaining his decision to accept the Einstein job, Purpura said he had served as a consultant to the search committee at Einstein for several months assisting it in the recruitment of a new dean.

A Yeshiva University press release announcing the appointment quoted President Lamm as saying that the search committee for a dean was "electrified" when it learned that Purpura had stepped down as dean at Stanford and was available. "They know him as a brilliant scientist, a skillful administrator and a charismatic educator whose talents enriched Einstein for 15 years," Lamm added.

Stanford University President Donald Kennedy said, "Dom Purpura's scientific accomplishments and scientific judgment should make him an outstanding dean at Albert Einstein College of Medicine."

Purpura said his new job at Einstein matches his stated academic and scientific objectives. He said he sees as priorities the further enhancement of the biomedical and behavioral sciences, and the patient care and research programs at the Bronx Municipal Hospital Center and Montefiore Medical Center, with which the medical school is closely allied.

Prior to coming to Stanford, Purpura, a Harvard Medical School graduate, had served as director of the Rose F. Kennedy Center for Research and Mental Retardation and Human Development at Einstein. He was also the first chairman of the department of neuroscience.

NEW TREATMENT REGIMEN MAY ELIMINATE OFTEN-LETHAL ABNORMAL FORMATIONS IN BRAIN

STANFORD—

Physicians at Stanford University Medical Center and University of California, Berkeley have developed an experimental three-pronged treatment regimen aimed at obliterating often-lethal abnormal blood vessel formations in the brain.

The abnormalities, called arteriovenous malformations (AVMs), are often lodged deep in the brain, rendering them inoperable—and untreatable—for fear of damaging the vital surrounding brain area. Up to 2,000 people nationwide each year, usually under the age of 30, suffer from the congenital condition that, left untreated, kills up to 25 percent of its victims, said Dr. Gerald Silverberg, associate professor of neurosurgery at Stanford.

Now, he and his colleagues are optimistic about the combined effects of surgery and two techniques developed in the last decade that have never been used together on these inaccessible malformations before. By shooting minuscule pellets up to block off the abnormal vessels, operating on the accessible vessels, and then irradiating the residual portions of the malformation, Silverberg said they may finally have a method of treating a condition for which, until now, therapy options were limited.

"The radiation, done at UC Berkeley with the only synchrocyclotron accelerator in the western world specially adapted for medical use, is the definitive treatment," said Dr. Jacob Fabrikant, professor of radiology at UC Berkeley and University of California, San Francisco. The special accelerator has been adapted to send out helium ion beams that can be directed within one-tenth of a millimeter. "No other type of radiation is this precise. We can irradiate exactly the area we want, and not one millimeter more," Fabrikant said.

Because radiation is most effective on as small a mass as possible, the other two steps are geared at decreasing the size of the malformations, he explained.

Resembling a mass of tangled red spaghetti, AVMs consist of abnormal blood vessels that disrupt the normal blood flow through the brain, stealing the essential blood supply that feeds the brain. The malformations can go unnoticed, Silverberg said, or they can cause symptoms including hemorrhage, seizures, severe migraine-like headaches, or deterioration of brain functions such as speech or motor control.

The new experimental three-pronged regimen has been used to treat eight patients since January, Silverberg said. All are doing well, he added, but more follow-up time and more patient cases are needed to reach definitive conclusions before the procedure can be made more generally available.

The first of the three steps is a procedure done by only a few because of its tediousness, difficulty and danger to the patient, said Dr. William Marshall, professor of radiology (clinical) at Stanford. Called embolization, it works on the basis that the body's arterial system is all connected; once something gets in the blood stream it can travel anywhere in the body.

The radiologist inserts a catheter—a thin, hollow tube—into the artery in the leg and guides it up towards the malformation. Through it the radiologist may send an inflatable balloon or another smaller catheter that rests against the normal blood vessels to form a protective shield for the normal circulation.

The radiologist then shoots up tiny pellets, Marshall continued, ranging from half a millimeter to 1.5 millimeters in size. The pellets, made of plastic, lodge in the abnormal blood vessels, blocking the blood from flowing through the abnormal vessels and forcing it to flow the normal route.

"We can use anywhere from 20 to several hundred pellets," Marshall said. "You can't see where they're going as you're shooting them in, so you take sets of X-rays after you inject every 10 or so beads."

The procedure can also be used to block off the blood supply that feeds tumors, he added, and in rare cases, to circumvent nosebleeds.

Next, the neurosurgeon surgically removes any part of the malformation that has not been blocked off and is accessible. The last step involves the radiation treatment, which essentially kills the remaining abnormal blood vessels by clotting and eventually stopping the blood from flowing through them. By decreasing the blood flow, Fabrikant said, it's possible to decrease the size of the malformation until it completely disappears.

"If we can reduce the size of the AVM with embolization and surgery as preparation for radiation, we have a better chance of obliterating it," he explained.

In an article just published in *The British Journal of Radiology* Fabrikant and colleagues reported the first clinical results of using only radiation to treat the malformations. It "...appears to be a safe, reliable, and potentially efficient alternative," he concluded.

ALCOHOL STUDY SEEKS FEMALE VOLUNTEERS

STANFORD—

About 10 more volunteers are needed by the end of next week to participate in a study designed to examine the effects of alcohol on blood pressure and cholesterol levels.

Researchers, headed by Dr. Peter Wood, deputy director of the Stanford Heart Disease Prevention Program, are seeking non-smoking females ages 25-40, in general good health, with normal menstrual cycles (not on oral contraceptives), who are light to moderate drinkers.

Volunteers will receive free blood pressure screening, cholesterol evaluations, and diet composition analysis, said Dr. Marcia Stefanick, a postdoctoral fellow involved in the study. She explained that previous studies on the effects of alcohol intake on blood pressure and cholesterol levels have focused primarily on men.

Participants will be asked to consume no fewer than one and no more than three drinks a day for a month, Stefanick said—a drink meaning one beer, one 4 oz. glass of wine, or one ounce of hard liquor. Then, the women will be randomly divided into two groups: one to stop drinking for a month, the other to continue the regimen.

The project requires several clinic visits for blood drawing, and two days of ambulatory blood pressure monitoring (through a device participants can wear and carry with them), Stefanick said.

Social drinkers concerned about maintaining good health while contributing to science should call (415) 497-7820, 10 a.m.-12 noon or 2-4 p.m. weekdays, for further information.

DEPRESSION AMONG ELDERLY TOPIC OF STUDY

STANFORD—

Stanford University Medical Center researchers are trying to determine if psychotherapy is effective treatment for depression among the elderly and if so, whether certain traits make individuals respond better to one type of therapy compared with another.

"Depression is the most common mental health problem among the elderly, yet there has never been a large study to determine effective treatment for it," said Dr. Julia Steinmetz, coordinator of the project.

In a four-year study funded by the National Institute of Mental Health, principal investigators Drs. Larry Thompson and Delores Gallagher of the Palo Alto Veterans Administration Medical Center plan to treat as many as 150 people between 60 and 80 years old for depression with three different types of psychotherapy.

Many older people aren't aware of what depression is, nor that they may be suffering from it, Steinmetz explained. "We do a lot of education in the community to let people know what depression is, that it isn't uncommon, that it can be treated, and they aren't considered crazy if they are depressed."

Participants in the study must be analyzed as having depression as their main problem, and not as the result of another problem, Steinmetz said. The condition often stems from a loss of mate or job, or change in financial status, and can be characterized by feeling down or apathetic. Symptoms of depression, she elaborated, can include guilt, sleep problems, appetite problems, fatigue, thoughts of death or suicide, indecisiveness, lack of concentration, or loss of interest or pleasure.

Those who qualify for the study are individually treated with one of three different types of therapies for four months. During the first month, they see the therapist two times each week, and for the remaining three months, once a week.

"One of the things we're looking at is if these therapies provide a good alternative to drug therapy," Steinmetz continued. Many elderly people hesitate to take drugs, she explained, because their bodies can't handle the side effects or simply because they don't like them. "Many people we're treating have tried drugs and didn't like the way they worked," she said.

The therapies used are cognitive therapy, which states that people are depressed because of the way they think, Steinmetz explained. Behaviorial therapy is based on the assumption that people are depressed because of the quality and kinds of activity in their lives. With both types of therapies patients learn skills to modify their ways of thinking and doing different things, Steinmetz said.

Psychodynamic therapy, the third type of therapy offered, is a more traditional type in which patients and therapists discuss the patient's past and try to reach an understanding about it. "It's not as perscriptive a therapy because the therapist isn't giving the patient a new skill," Steinmetz said.

The study, which began in 1982 and continues until 1986, is based at the Center for the Study of Psychotherapy and Aging at the Menlo Park division of the Palo Alto Veterans Administration Medical Center. For more information call (415) 858-3989.

BLOOD SUPPLIES SERIOUSLY LOW, STANFORD BLOOD CENTER REPORTS

STANFORD—

Stanford University Blood Center is extending its hours for donations this week because of a critical shortage of blood which could result in patients doing without needed transfusions, medical director Dr. Edgar Engleman announced Monday (July 16).

"We are in a situation today where a major accident or serious surgery could completely deplete our reserves of certain types of blood," Engleman said.

Engleman, an associate professor of pathology and medicine, said reserves are frequently lower in the summer when regular donors are away from the area on vacation and emergencies requiring transfusions tend to make usage high.

But the current shortage, Engleman explained, is worse because blood banks nationwide have tended to cut back on recruitment efforts during the past year in response to a general decline in the need for blood. He speculated that the temporary drop in usage may have resulted from persons postponing elective surgery for economic reasons.

The mistaken concern that giving blood can expose donors to acquired immune deficiency syndrome (AIDS) has resulted in a 2 to 3 percent drop in donors during the past 12 months, "but this has been a relatively minor factor in the current shortage," Engleman said. (Blood transfusions can sometimes expose recipients to AIDS, but Stanford has intiated a screening test for that ailment.)

"Ordinarily, we can simply make a phone call to a nearby center to get needed blood," Engleman said, "but we're finding that these centers are equally low. We just simply don't have the reserves anywhere in the area. Without some help soon, it is indeed possible that a desperately ill patient might have a transfusion delayed because of the area-wide shortage."

"Four times during the past two weeks we have been in situations where we have had to really scramble to find adequate amounts of blood while a surgical procedure was actually underway," Engleman said.

The blood center normally keeps a reserve of 240 units of blood of various types. The inventory, said Rhoda Burns, supervisor of blood donor recruitment, is down to 36 units.

To replenish supplies, the blood center at 800 Welch road in Palo Alto will remain open every evening this week through Friday, July 20, from 8:30 a.m. until 7:30 p.m., an extension of evening hours.

Although normally closed on Saturday, the center will be open from 10 a.m. to 2 p.m. Saturday, Burns added.

Appointments are not necessary, Burns said, but persons wishing further information may call the blood center at (415) 497-7831.

(Editors, reporters: Engleman may be contacted directly at (415) 497-7960.)

GRATEFUL FATHER WALKS FOR INTENSIVE CARE NURSERY

Photos available upon request if not included.

STANFORD—

A one-man walkathon over the weekend raised almost $2,500 for the intensive care nursery (ICN) at Stanford University Hospital, said Thomas Eastin, the walker who completed his 75-mile trek up from Salinas Sunday evening.

The father of a baby boy, Jeffrey, whose life was in danger at birth last spring, Eastin had vowed to undertake the personal walkathon if his son lived. He "felt he had to do something" for the ICN, said his wife, Cindi.

Walkathon donations included pledges from family and friends, as well as a few $5 and $10 cash gifts spontaneously handed to Eastin, who wore a T-shirt emblazoned "Stanford or Bust" en route. Also, a $500 check was presented by registered nurse Nancy Abel, on behalf of a grateful family whose own child is on the unit.

The walkathon was "the hardest thing I ever did in my life," said a weary Eastin as he was greeted at the hospital by welcome signs and balloons, champagne, a waiting room full of family and friends, nursery staff, and two soothing basins of water for his aching feet.

Dr. Philip Sunshine, professor of pediatrics and director of newborn nurseries, said the money raised will be used to help parents from outside the Stanford area who otherwise couldn't afford to visit their desperately ill babies in the ICN. The money, he said, might also be used to help pay to bring back babies after their release from the hospital for follow-up research studies which might improve patient care for future patients.

Paul Edwards, associate director of medical development at Stanford, said he plans to meet with Cindi Eastin Tuesday, July 17, to accept gifts and pledges garnered by her husband.

TEEN'S WEIGHT-LOSS CAMP STARTING SOON

STANFORD—

The second session of Stanford's summer weight-loss day camp is scheduled from July 23-August 16, announced Dr. Mary Southam, the psychologist who runs the camp.

The session for teens ages 12-17 is being offered again in response to the popularity of the first session earlier this summer. The campers' aim is to have fun while slimming down through peer and parent support, as well as behavior modification in eating and exercise, Southam said.

The children's session will run from 9 a.m. to 1 p.m., four days per week. Lunch is included. Swimming, tennis, and active games will be emphasized.

Faculty includes members of the behavioral medicine program of the school of medicine. A fee is charged.

Early enrollment is recommended, as space is limited. For further information, call Southam at 415-497-5065.

(Editors, News Directors: Eastin plans to arrive at the Neonatal Intensive Care Unit at Stanford University Hospital at 6 p.m., Sunday, July 15, where the staff—many of whom knew the Eastins during Jeffrey's long hospitalization—plans a brief and informal welcoming ceremony. Photographers and reporters are welcome. Charlene Canger, clinical social worker on the unit, will be available for media questions on Sunday, at (415) 497-7200. A member of the Medical Center news bureau staff may also be contacted during the weekend through (415) 497-6661. Ask for the news bureau representative on duty.)

SALINAS MAN PLANS WALKATHON TO FULFILL VOW FOR ILL SON

STANFORD—

Thomas Eastin plans to walk 75 miles from Salinas by Sunday to visit the intensive care unit at Stanford Medical Center where physicians last May had predicted the death of his newborn son, Jeffrey.

Eastin, 30, a juke box and electronic game vendor, said Thursday (July 12) he had raised about $500 in pledges from friends and families for the personal walkathon he'd vowed to undertake if his son recovered.

"I know it sounds corny," said Eastin, but after the doctor told him his son would probably die, "I started praying and stuff. I asked God, 'If you do this for me, I'll do this (the walkathon) for You.' "

A few hours after the boy was delivered at Salinas Valley Hospital on April 12, he was airlifted to Stanford University Hospital, where he stayed until May 29.

Jeffrey suffers from kidney failure caused by an obstruction and cysts, said Dr. Michael Trautman, a Stanford physician who took care of the boy during the most critical first weeks of life. When Jeffrey was admitted to the hospital, Trautman said the baby suffered from persistent fetal circulation, a heart and lung disease. High blood pressure from the right side of the heart backs up into the lungs. This condition, known generally as pulmonary hypertension, is caused by the infant's inability to switch over from fetal circulation to the normal blood flow of a newborn baby.

Trautman, who had told Eastin his son would likely die, said the boy's heart and lung problems now appear to have been corrected but a kidney transplant or dialysis will probably be needed within a few years to compensate for permanent damage to that organ.

July 12, 1984

-more-

Now back in the care of both Dr. Bruce Tune, a Stanford kidney specialist, and Salinas pediatrician Dr. Donald King, Jeffrey is "alert, sociable and goos and looks quite normal" despite his long-term problems, said his mother, Cindi, who is painfully aware her son "is not out of the woods yet."

Eastin, who said he jogs about three to five miles a day after work, said he got the idea for the walkathon from a movie which depicted a similar event. He said he will accept pledges per mile of any amount and will turn any proceeds over to the neonatal intensive care unit's general fund. He said he hopes to raise about $1,000.

Dr. Philip Sunshine, director of newborn nurseries, said the money will be used to help parents from outside the Stanford area who otherwise couldn't afford to visit their desperately ill babies in the intensive care nursery. The money, he said, might also be used to help pay to bring back babies after their release from the hospital for followup research studies which might improve patient care for future patients.

Cindi Eastin, 29, said her husband decided to go ahead with the walkathon because he "felt he had to do something for the (intensive care) unit."

Eastin said Thursday he plans to put on a pair of old jogging shorts and a new T-shirt emblazoned with "Walk for Stanford," and start walking Friday night down Reservation Road, U.S. 101, and Monterey Road to San Jose, where he will trek The Alameda to El Camino Real for the final leg of his journey up the peninsula to Palo Alto and Stanford by Sunday afternoon.

He said his older son, Thomas Jr., 5, may accompany him on the last leg. Cindi, and perhaps Jeffrey and the couple's daughter Kelly, 2, might drive up for a brief and informal reunion Sunday at the intensive care nursery.

Cindi Eastin said persons wishing to pledge a contribution for the walkathon may call her at (408) 449-8073 or (408) 422-0079. All proceeds would be turned over to the Stanford University Medical Center for use in the neonatal intensive care unit.

Paul Edwards, associate director of medical deveolopment at Stanford, said he plans to meet with Mrs. Eastin on Tuesday (July 17) to accept gifts and pledges.

STANFORD RADIATION BIOLOGIST WINS DANISH AWARD

STANFORD—

Dr. Kendric C. Smith, professor of radiology at Stanford University School of Medicine, was awarded the Finsen Prize in June at the Ninth International Congress on Photobiology in Philadelphia.

The award, for outstanding contributions to the science of photobiology, is presented every four years by the Assocation Internationale de Photobiologie on behalf of Denmark's Neils Finsen Foundation.

The Finsen Foundation was established in honor of the Danish scientist Neils Finsen, who received the Nobel Prize in medicine in 1903 for his work on the healing and damaging effects of sunlight on skin, Smith said.

Smith, who has been a Stanford faculty member since 1962, conducts research on the genetic control and biochemical basis of repair to the hereditary material, DNA, in cells damaged by ultraviolet radiation and by x-rays. He also studies the role of DNA repair in spontaneous and radiation-induced mutagenesis—chemical modification of DNA.

Smith was the founding president of the American Society for Photobiology, and has written or edited several books and journals on photobiology. He is also the immediate past president of the 6,000-member American Institute of Biological Sciences.

VOLUNTEERS NEEDED FOR HUMAN SEXUALITY STUDY

STANFORD—

Stanford University Medical Center is looking for volunteers to participate in studies aimed at explaining the role of biologic factors in human sexual behavior.

Dr. Julian Davidson, professor of physiology, is conducting three studies looking at the role of hormones, aging, and neurotransmitters in the brain.

For the first study, he is seeking about 20 adult men of all ages. Participants will be asked to attend three sessions, during which they will have blood samples taken for hormone analysis. They will also be assessed, by questionnaires and observation, for their physiological responses to visual erotic stimuli and other tests.

Participants in the second study will be testing the effects of a drug that may be therapeutic for men suffering from sexual dysfunction, Davidson said. He is looking for about 40 men of all ages who are impotent or have inhibited sexual desire. Participation is required for about two months, during which the men will receive the drug and a placebo. Measurements of the medication's effectiveness will be similar to the methods of the first study.

Davidson is seeking about 40 women to volunteer for the third study, which will be investigating the effects of hormone replacement therapy in postmenopausal women. Participants should be at least one year past menopause, and should not have taken any hormone treatments with the last three months. They should be in good health.

The study will last for about four months, and participants will be asked to make about nine visits to the laboratory. They will receive either one hormone or a combination of hormones, or a placebo. Effectiveness of the hormones will be assessed by questionnaires and observation of their physiological responses to visual erotic stimuli.

For information about these studies, call Davidson at 415-497-2432 or 415-497-9156.

ADVANCE FOR RELEASE JULY 4 AFTER 3:30 P.M. PACIFIC DAYLIGHT TIME

SCIENTISTS DISCOVER THAT A CANCER MAY BE COMPOSED OF TWO TYPES OF CELLS

STANFORD—

Treatment of one form of cancer with certain drugs or monoclonal antibodies tailormade to recognize and destroy malignant cells is likely to be more complex than previously thought, Stanford University School of Medicine scientists reported July 5 in the *New England Journal of Medicine*.

The scientists reported that cancers may be composed of two types of cells, challenging the longstanding assumption that all cells in a tumor are genetically identical because they descended from one original cell that went awry, said Dr. Jeffrey Sklar, assistant professor of pathology at Stanford University School of Medicine.

The implication for future therapy is that physicians will now have to be alert to look for more than one cell clone in biopsies of cancerous tissue, Sklar said. And new therapies where drugs are specifically selected or other agents are tailor-designed to recognize and destroy a single malignant cell clone may instead require more than one drug or antibody to recognize all the tumor's different cell clones, he added.

The discovery was made in patients with B-cell lymphoma, a cancerous growth of the immune system's antibody-producing cells. The scientists found that 20 percent of a group of B-cell lymphoma patients possessed a "biclonal" tumor, composed of two genetically distinct cell clones.

The research was reported in the July 5 issue of the *New England Journal of Medicine* by postdoctoral scholars Dr. Michael Cleary and Dr. Kristiaan Thielemans, research assistant Julie Gralow, associate professor of pathology Dr. Roger Warnke, Dr. Ronald Levy, associate professor of medicine, and Sklar.

The work was supported by grants from the American Cancer Society and the National Institutes of Health, and by fellowships from the John A. Hartford Foundation and the Jane Coffin Childs Memorial Fund for Medical Research.

The finding came about, in part, as an attempt to study tumors using monoclonal antibodies tailored to attack individual patients' lymphomas. In an experimental program run by Levy at Stanford, twenty lymphoma patients are currently being treated with or evaluated for anti-lymphoma monoclonal antibody therapy.

-more-

In light of the new finding, the researchers now have uncovered a group of lymphoma patients for whom single antibody therapy could potentially be inadequate. Because the treatments are designed to recognize only one type of cell, a second group of cancerous cells in a biclonal tumor could continue to multiply, unaffected by therapy, Sklar explained.

The discovery of biclonal tumors also makes diagnosing some cases of B-cell lymphoma more complex, Sklar said. In hard-to-diagnose cases, physicians can no longer rule out cancer on finding more than one clone in a biopsy sample, he explained.

While the finding makes tailormade cancer therapies more complex, new strategies may be developed to circumvent these problems, Sklar predicted. But it will be necessary to take more biopsy samples from several sites in the patient's body to make sure that all clones in a patient's tumor have been detected. Then, one or more drugs or antibodies recognizing all the tumor's different cell clones could possibly be used for therapy, Sklar said.

B-cells participate in the body's disease fighting immune response by producing antibodies, proteins that specifically recognize foreign material, including microbes such as bacteria.

All B-cells start out genetically identical. But as they mature, rearrangements occur among the pieces of the hereditary material—DNA—encoding instructions for making antibodies.

This gives every B-cell its own distinctive DNA "fingerprint," Sklar explained. If one of these cells becomes cancerous and starts dividing to create a B-cell lymphoma, all its descendants that form a tumor would also have the same DNA fingerprint, scientists believe.

But by using monoclonal antibodies in sophisticated cell sorting techniques and then looking at the DNA rearrangements in sorted tumor cells, the Stanford group found that not all of an individual's cancerous cells possessed the same DNA fingerprints. In four out of 20 cancers examined, the scientists found biclonal tumors, composed of two distinctive cell types.

The finding may help researchers understand more about how B-cells develop, and how B-cell tumors arise, Sklar said. In one of the patients studied, there is evidence that the two cancerous clones are related, and may both have descended from a B-cell precursor that had turned malignant.

In the other three patients, the scientists cannot yet say whether the two clones became cancerous independently or share a common cancerous precursor.

NEW RH-FACTOR ANTIBODY DEVELOPED FOR PREGNANT WOMEN

STANFORD—

Stanford researchers have developed a new monoclonal antibody that could protect thousands of unborn infants from attack by their mothers' immune systems.

Injections of the genetically engineered antibody could prevent destruction of a fetus' red blood cells due to Rhesus (Rh) factor blood type incompatibility between mother and child.

Rh-factor incompatibility in pregnant women has been controlled in recent years by giving an expectant Rh-negative mother blood serum that neutralizes the immune attack against an Rh-positive baby's blood.

Although effective, this serum is becoming increasingly scarce, said Dr. Nelson Teng, assistant professor of gynecology and obstetrics at Stanford University School of Medicine. Also, when using blood products there is always a small chance of accidental contamination with blood-borne diseases such as hepatitis, cytomegalovirus, or possibly AIDS, he noted.

"This new way of generating pure Rh-factor antibodies in the laboratory is promising and would circumvent the potential contamination problem as well as the production problems involved in getting Rh-antibodies from blood," Teng said. It would be a more widely available, simpler, and safer procedure for the 15 percent of the female population that is Rh-negative, Teng predicted.

The antibody is currently being tested in the laboratory for efficacy, said Teng. Clinical trials in humans are planned in the near future, he said.

Creation of a cell line that steadily produces the antibody was reported in a recent issue of the scientific journal, *Proceedings of the National Academy of Sciences*. Teng's colleagues in the research are postdoctoral scholar Dominique Bron from Belgium, medical student Mark Feinberg, and the late Henry Kaplan, who was a world-renowned Stanford University cancer specialist.

When a woman with Rh-negative blood marries a man with Rh-positive blood, there is a high probability that their children will be Rh-positive. This can lead to hemolytic disease of the newborn, a condition in which the mother's immune system attacks the fetus' red blood cells during pregnancy, Teng explained. Jaundice, developmental problems, mental retardation, and even death of the infant may be the result.

-more-

During an Rh-negative woman's first pregnancy, an Rh-positive baby is usually safe because its mother's immune system has not yet been sensitized to Rh-positive blood, Teng explained. But when the baby is delivered, some of its Rh-positive blood cells can leak into the mother's bloodstream. These Rh-positive cells, foreign to the mother's immune system, cause her to generate anti-Rh antibodies.

In subsequent pregnancies with Rh-positive babies, the mother's antibodies can move across the placenta into the fetal circulation, destroying the baby's red blood cells, Teng explained.

To prevent this from happening, the mother is injected with serum containing anti-Rh antibodies shortly after delivery of her first child. These antibodies destroy the foreign red blood cells before the mother's immune system can build defenses against them.

The serum is obtained from untreated Rh-negative women who have borne Rh-positive children, or from Rh-negative volunteers who have been exposed to Rh-positive blood. "Since most Rh-negative women currently receive prophylaxis against the Rh factor, there are fewer available to provide serum," Teng explained.

The new pure monoclonal antibody is made in cells called hybridomas. The hybridoma cell line was created by Teng and his colleagues, who fused a human lymphoid cell that produces anti-Rh antibody with a tumor cell able to divide continuously. The fused hybrid cell is a source of continuous, pure human antibody, Teng explained.

Because human tumor cells do not easily fuse, the researchers used a cell that was itself a hybrid, obtained by fusing a mouse cell with a human cell. This technique is being used to generate other medically useful monoclonal antibodies, Teng said.

In addition to its potential clinical use, the pure anti-Rh antibody will be useful for blood group typing, and for biochemical and genetic studies of the human Rh system, whose functions are poorly understood, Teng said.

Funding for the research came from the National Cancer Institute and the Robert L. Seidner Research Fund. Postdoctoral support came from the Rose et Jean Hoguet Foundation of France, and the North Atlantic Treaty Organization.

KNOWLEDGE ABOUT MEDICAL AFTERMATH COULD HELP PREVENT NUCLEAR WAR, PHYSICIANS SAY

STANFORD—

The more knowledgeable people are about nuclear war's medical consequences, the more likely they are to oppose nuclear war, a group of anti-war physicians has discovered.

The finding is based on a questionnaire survey testing peoples' knowledge and opinions about nuclear war, conducted by Physicians for Social Responsibility (PSR), a group devoted to educating people about the medical aftermath of nuclear conflict.

People who scored highest on nine factual items in the survey questionnaire were least likely to agree with the statement, "there are causes worth fighting a nuclear war for," reported Dr. Perrin French, a PSR official, in an article in the September issue of *Psychology Today*.

The questionnaire was administered at 57 educational forums sponsored by PSR in the San Francisco Bay Area between February 1981 and October 1982, said French, a clinical assistant professor of psychiatry and behavioral sciences at Stanford University School of Medicine.

A total of 1,355 people completed the "Nuclear War Attitude Survey" before and after a film or slide show and discussion of the effects of a nuclear exchange, French said.

Before the presentation, "approximately 10 percent of those questioned said they could countenance nuclear war," French noted, and "the greatest proportion of acceptors of nuclear war were people with the fewest correct answers on the factual portion of the test."

Following an informational slide or film presentation, nearly 50 percent of the people who originally felt there might be a cause worth waging a nuclear war for changed their opinion, French said. Two percent of those originally opposed to any nuclear conflict shifted their view to favor nuclear war in some situations, he added.

PSR, whose members number almost 24,000, undertook the study to test the validity of its assumption that "increased knowledge about the nature and effects of nuclear weapons will produce a worldwide climate of restraint conducive to avoiding nuclear war," French explained in the article, and to evaluate how effective the group's efforts actually were.

"Since opinion on these matters changed readily in one direction, it is possible that it could change back as readily in the other direction," French wrote.

"But our survey did show an initial change, and it is the hope of a rapidly growing number of scientists that efforts to increase knowledge about nuclear weapons and their medical effects will lead to enduring attitude change, reducing both the acceptability and likelihood of nuclear weapons use," he concluded.

The Stanford chapter of PSR was formed in 1981 by French and three medical students. It now has over 800 members, several hundred of whom are non-physicians, French said. Those interested in the organization should call Sylvia Rogers at (415) 497-9060.

RADIATION TREATMENTS HELP KIDNEY TRANSPLANT PATIENTS SURVIVE WITH FEWER DRUGS

STANFORD—

Total lymphoid irradiation (TLI), a form of radiation therapy originally developed to treat cancer, is now helping kidney transplant patients survive with minimal drug therapy, transplantation researchers reported Aug. 29 and Aug. 31 at the International Congress of the Transplantation Society in Minneapolis.

The therapy helps control rejection, the body's tendency to attack and destroy foreign tissue, without the usual powerful doses of anti-rejection drugs, said the researchers from Stanford University School of Medicine and Pacific Medical Center in San Francisco.

The technique involves a form of radiation developed in the 1950s by Henry Kaplan and other Stanford researchers, to treat Hodgkin's disease, a cancer of the lymphatic system. TLI limits the body's ability to reject foreign tissue because it suppresses the immune system.

Almost all kidney transplant patients given conventional treatment develop an immune attack, called a rejection episode, on the foreign organ within the first year following surgery, explained Dr. Samuel Strober, professor of medicine at Stanford. If the rejection episode is severe enough then the new kidney will be lost, he added.

But so far, nearly three-fourths of the patients receiving the experimental treatment have completed the first year after surgery without a rejection episode, he said.

Furthermore, these patients take only low doses of a single anti-rejection drug, Strober said. In contrast, kidney transplant patients with conventional treatment programs take several drugs at high doses, often with debilitating side effects, he explained.

The new treatment combines radiation prior to transplant surgery and drugs following the operation. Because the anti-rejection effects of TLI are long-lasting, only a low dose of the drug prednisone is needed to prevent rejection after surgery, Strober explained.

"This is a highly promising technique for controlling rejection in kidney transplant patients," Strober said. "Its greatest advantage is that it eliminates dependence on the major anti-rejection drugs, many of which have undesirable side effects when used continuously."

Strober and his colleague Dr. Barry Levin, a nephrologist from Pacific Medical Center, reported preliminary results on 19 patients in two presentations Aug. 29 and 31 at the International Congress of the Transplantation Society in Minneapolis.

Strober noted that continuing trials are needed to determine the long term effectiveness and safety of the new therapy.

8-31-84 -more-

Their other colleagues in the research were the late Dr. Derek Sampson, who had been a transplant surgeon at Pacific Medical Center, Dr. Richard Hoppe, radiotherapist at Stanford, Dr. Charles Bieber, formerly in the Stanford cardiovascular surgery department, Elizabeth Miller and Dr. Marc Waer, both from Strober's lab at Stanford, the late Dr. Henry Kaplan, radiologist at Stanford, and Dr. Geoffrey Collins, transplant surgeon at Pacific Medical Center.

Nearly 80 percent of kidney transplant patients who receive the anti-rejection drug cyclosporine, introduced in recent years, maintain a functioning kidney at least one year, Strober said. The new experimental protocol has achieved as high a survival rate for the transplanted kidney without using cyclosporine, he noted.

"Because cyclosporine's potential side effects include kidney damage, high blood pressure, and lymphoma, a cancer of the lymphatic system, we would like to avoid using it on a continuous basis if possible," Strober said.

In addition to eliminating the need for cyclosporine, the new treatment does not depend on the use of azathioprine (Imuran), another traditional anti-rejection drug with adverse side effects, Strober said.

The only drug taken by kidney transplant patients on the new protocol is prednisone, a synthetic drug that mimics the action of a natural body hormone called cortisone, Strober explained. The prednisone dose patients take is so low that it is close to natural cortisone levels in the body, he added.

The new results are particularly promising, Strober mentioned, because several diabetics are among the 17 patients doing well on the protocol. Normally, diabetics have low survival rates following kidney transplantation, because high doses of prednisone complicate their disease, he explained.

For several months prior to transplant surgery, patients receive a series of TLI treatments, totaling 2,000 rads, in which low doses of x-rays are beamed at the body's major lymph tisses in the neck, chest, abdomen, thymus and spleen.

The irradiation suppresses the immune system, which is responsible for tissue rejection, without seriously compromising the patient's ability to fight infections, Strober explained.

Following surgery, the patients are given a single large dose of a potent anti-rejection preparation called rabbit antithymocyte globulin. Thereafter, unless rejection sets in, prednisone is the only drug patients receive.

The side effects during TLI therapy are modest and temporary, Strober said, usually limited to nausea, fatigue and and depletion of certain blood components.

The most frequently observed complication after transplantation was infection by herpes virus, but these infections can be rapidly controlled with antiviral therapy, Strober reported. The only fatality of the study was one patient with a herpes infection who died while simultaneously undergoing rejection, Strober said.

Funding for the studies comes from grants from the National Institutes of Health.

FOR IMMEDIATE RELEASE

"COHEN-BOYER" GENETIC ENGINEERING PRODUCTS PATENT ISSUES

STANFORD—

A patent sought by Stanford University, covering genetically engineered molecules that can be used to develop and generate biological products in bacteria, was issued today (Aug. 28) by the United States Patent and Trademark Office, university officials said.

The patent, based on an application filed 10 years ago, is the companion to a broad patent issued in 1980 covering the basic gene cloning process.

The 1980 "process" patent covers the basic method of splicing and recombining genes to create a recombinant DNA molecule with a foreign gene it doesn't normally contain. The new "products" patent covers these recombinant DNA molecules and their uses in bacteria.

Both patents are based on work carried out in 1973 by Stanley N. Cohen, professor of genetics at Stanford University School of Medicine, and Herbert W. Boyer, professor of biochemistry at the University of California (UC) in San Francisco.

The two patents give Stanford a proprietary position—until 1997—over the basic methodology and tools currently used throughout the biotechnology industry, said Niels Reimers, director of Stanford's office of technology licensing.

Industries use the lab-constructed molecules containing DNA from two different species of living things, in bacterial "factories," to develop and produce large quantities of previously scarce but valuable substances including vaccines, drugs, and hormones.

The spliced DNA molecules also permit scientists to conduct vital research revealing the molecular structure and organization of genes themselves.

The new patent is significant because the Patent Office has confirmed basic rights granted in the original gene cloning methods patent, said Reimers.

"We believe that virtually all genetic engineering companies are using this patented technology in their research and development," said technology licensing associate director Katharine Ku, who is responsible for recombinant DNA technology licensing at Stanford.

"Although as of early August, 66 companies had licenses, we now expect that all other companies doing commercial research will also take licenses," Ku added.

To date, many scientific research products derived using the patented invention have become commercially available, although only one pharmaceutical product is out for sale to the public, Ku said. It is a bacterially produced form of human insulin, called "Humulin," developed by Genentech and marketed by Eli Lilly. Several other products are nearing commercial availability, including a hepatitis B vaccine, human interferon, human growth hormone, and a drug for treating emphysema, she added.

-more-

Stanford and UC share revenues accrued through licensing of these patents. So far, they have received slightly less than $3 million, Reimers noted. He added that the two universities do not expect significant earned royalties from the patents until later in this decade.

Royalties are used for educational and research purposes at the two universities, Reimers said. Both Cohen and Boyer have waived rights to personal royalties.

"This is an extraordinarily basic patent," said Reimers. "The patent office thoroughly reviewed a number of outside objections lodged against the application, and clearly found them wanting."

The patent application for both the gene cloning process and its products was filed originally in 1974 by Stanford on its own behalf and that of UC. Bertram Rowland is the patent attorney who is handling the case for Stnaford.

In 1978, the claims were separated so that the process application could be granted in Dec., 1980. Issuance of the products patent had been expected in 1982, but the Patent Office instead temporarily rejected the application, Ku noted, in order to consider some issues more fully.

These questions centered on the breadth of the claims, co-inventorship, "obviousness" of the invention, whether the application as filed enabled others to make use of the invention, and whether Stanford and Rowland fully disclosed all pertinent information.

"We are pleased that all these issues have been resolved during the application process," Reimers commented. "It has brought about a much stronger patent in the end."

To allow the present patent to issue as rapidly as possible, Stanford withdrew claims covering use of the spliced DNA molecules in "eukaryotes," complex unicellular organisms such as yeast, Ku said. These claims, which would give Stanford even broader coverage, are currently being pursued in a separate application, she added. The new patent gives Stanford coverage for the use of DNA molecules containing foreign genes, in simple single-celled "prokaryotic" organisms such as bacteria.

The issue considered most recently before the patent was granted concerned "duty of disclosure," based on section 1.56 of the patent and trademark part of the Code of Federal Regulations. In March, the Patent Office ruled that, although Rowland and Stanford should have advised them of certain pieces of information concerning coinventorship claims and inaccuracies in the original application, the omission was not an act of bad faith or gross negligence.

A major question about the patent application concerned whether or not it was "enabling"—accurate and detailed enough to enable other researchers to produce the genetically engineered DNA molecules described, Ku said.

The original application included a description of how a particular plasmid—a circular piece of DNA—was made. A later scientific report by Cohen revised his interpretation of how the plasmid molecule had been formed. The Patent Office's concern was that Rowland and Stanford had not told them about the article, and others who wished to make and use the plasmid might not be able to, due to the inaccurate interpretation contained in the application.

However, the Patent Office decided that the mistaken interpretation did not present grounds for rejection. Rowland and Stanford had argued that the plasmid had been given out freely by Cohen and Boyer to scientists who requested it, and that the basic genetic engineering process described in the patent application had been proven to work in creating other functional plasmids in laboratories around the world. .

"The Patent Office accepted our arguments that the application was enabling despite some question about the origin of one particular plasmid used in the first successful experiments," Reimers said.

"The Patent Office also ruled that recombined DNA molecules from different species are not 'products of nature,' an issue that was raised," Reimers added.

Another issue involved a collaborator in the original gene cloning experiments, Robert B. Helling, who at one time believed himself to be a coinventor.

Although Helling declined to sign a disclaimer of inventorship, he provided no evidence to support his assertion that he helped conceive of the gene rearrangement experiments, said Reimers.

Although the Patent Office said that Rowland and Stanford should have reported Helling's allegation to them, after investigating the evidence submitted by Rowland and by Helling himself, the Patent Office concurred that only Cohen and Boyer were the coinventors.

Other issues centered on a talk given by Boyer and whether or not the work of other researchers made the Cohen/Boyer work obvious.

According to patent law, an application must be filed within a year of public disclosure of an invention. One year and two months prior to the patent application filing date, an article appeared in the *New Scientist* magazine describing a private scientific conference in which Boyer participated. But the Patent Office decided that Boyer's talk and the article were not sufficiently detailed to cause forfeiture of the patent rights, Ku said.

The Patent Office also considered the work of other researchers who had proposed possible ways of making spliced DNA molecules prior to the Cohen/Boyer research. But the Patent Office ruled that these proposals did not contain the ingredients for successful gene cloning. "In issuing the patent, the Patent Office reconfirmed that Cohen and Boyer were the first to invent and successfully produce a biologically functional recombinant plasmid," Reimers said.

Normally patent prosecution is confidential. In the case of the Cohen/Boyer patents, Stanford asked for an open process that would allow public scrutiny and ensure that all potential objections might be raised, Reimers noted.

"These were groundbreaking patents," he explained, "and we preferred handling any potential challenges to them during the patent prosecution process rather than later on through legal channels."

However, in December 1982 Stanford asked the Patent Office to close the file. "We felt the open process was receiving undue attention in the media," Reimers recalled.

"Now that the patent has issued, the prosecution file history is available to the public and we encourage all interested parties to examine it," Reimers said.

The file will remain closed on the continuing application for gene spliced plasmids in eukaryotic organisms, he added.

VOLUNTEERS NEEDED IN DIABETES STUDIES

STANFORD—

The clinical research center at Stanford University Medical Center needs volunteers to participate in studies concerning the importance of nutrition in relation to health, specifically in people with diabetes.

Researchers, under the direction of Dr. Gerald Reaven, professor of medicine, are studying the effects of carbohydrate variations on the nutritional management of diabetes. To complete the study they need volunteers who have diabetes and are being treated with oral medication or by diet, but not with insulin injections.

All meals will be provided for volunteers during the one-month study. Participants will also receive a complete physical examination including laboratory tests, and a complete evaluation of their blood lipids including cholesterol, triglyceride, and high-density lipoprotein (HDL) cholesterol information.

Those interested in volunteering should call (415) 497-5430 between 9 a.m. and 4:30 p.m. for further information.

FIRST SCIENTIFIC STUDY TO SHOW THAT A FOLK APHRODISIAC STIMULATES SEXUAL ACTIVITY IN ANIMALS

STANFORD—

Stanford University Medical School researchers have reported the first scientific study showing that a folk medicine called yohimbine may stimulate sexual desire.

Along with substances such as bees' wings, camel's hump fat and rhinoceros horn, yohimbine has a long history as an aphrodisiac in folk medicine but a reputation as a "quack" love potion in the established medical profession.

The Stanford study, reported in the August 24 issue of *Science* magazine, shows for the first time that the drug strongly increases sexual drive in male rats.

This is an interesting observation because rats provide a good model for certain biological aspects of human sexual behavior, including libido or sex drive, explained Dr. Julian Davidson, professor of physiology.

However, Davidson cautioned that it is too soon to say whether the scientific evidence will prove that yohimbine is an effective aphrodisiac in humans. The drug's physiological effects in people may be different from those seen in rats, he explained. In addition, human sexual behavior is complicated by the influence of emotions and other factors, he added.

Davidson, whose research focuses on the biology of human sexual behavior, carried out the study with Dr. Erla Smith, acting associate professor of physiology, and Dr. Jack Clark, now doing postgraduate work at the University of Florida College of Medicine.

In a series of experiments, sexually active male rats injected with yohimbine mounted females about twice as frequently as did males given an inert substance, the researchers reported. In addition, yohimbine stimulated mounting behavior in both sexually inexperienced and sexually inactive male rats.

"The data suggest that yohimbine may be a true aphrodisiac," the researchers said. They added that "further research could lead to developments in pharmacologic treatment of sexual dysfunction."

"In our experience, this is the most powerful drug yet tested for stimulating sexual behavior in male rats," said Davidson. He noted that he and his colleagues are now studying the drug's effects in human volunteers. (No more volunteers are currently needed for the study, however.)

Although yohimbine originally was obtained from bark of the tropical tree *Corynanthe yohimbe*, it is now a synthetically manufactured prescription drug. In addition to its informal use as an aphrodisiac, yohimbine is also sometimes used for some heart problems, Davidson said.

It is thought to increase the activity of norepinephrine, a natural chemical that certain nerve cells use to communicate with each other in the brain, Davidson said.

Norepinephrine and related chemicals, called monoamine neurotransmitters, may be involved with controlling sex drive, Davidson suggested.

The work was supported by a grant from the National Institutes of Health.

JOHNSON APPOINTED MEDICAL CENTER ATTORNEY

STANFORD—

Rodney Johnson has been appointed Stanford University's managing attorney for medical affairs, replacing Ross Campbell, who is leaving to pursue a private law practice.

Johnson's appointment, effective Aug. 13, was made by John Schwartz, vice president for legal affairs, and announced jointly with Lawrence G. Crowley, vice president for medical affairs.

Since August 1980, Johnson has served as associate staff counsel in Stanford's legal office. He has represented the university in a variety of areas, including zoning and planning matters.

He served as counsel for Stanford's request to build the $117 million hospital modernization project in the Palo Alto city limits, and for the university's request to extend Willow Road eastward. In another area, he has represented the university on a variety of technology licensing matters.

Before coming to Stanford, Johnson practiced law in San Francisco. In 1981 he served as a member of the California North Central Coast (regional) Coastal Commission, a gubernatorial appointment to administer planning and other mandates of state coastal law.

Johnson is a 1973 graduate of the Columbia University School of Law and a 1970 honors graduate of Emory University.

Campbell, who was appointed to the medical center legal post in 1981, said he plans to open a Bay Area office for the Los Angeles-based law firm of Musick, Peeler and Garrett, which specializes in health care law.

OVERSEAS TRAVELERS NEEDED AS JET LAG STUDY VOLUNTEEERS

STANFORD—

Researchers are hopeful they can find enough volunteers meeting some unusual criteria to help cure one of mankind's newest medical problems—jet lag.

Wesley Seidel, a research assistant in the Stanford Sleep Disorders Center, said each of the 100 or so volunteers needed for the study must be healthy and willing to take one of several commonly dispensed perscription sleeping pills for three nights.

The catch, said Seidel, is that researchers are really picky about where volunteers take those sleeping pills. Volunteers are limited to persons who will be flying from the Pacific time zone to Tokyo or London within the next eight or 10 months.

The Sleep Center won't pay for the flight, said Seidel, but participants will be reimbursed $200 for their participation, including time and effort spent filling out a succession of forms documenting mood.

Seidel said the participants, who must meet specific criteria, will be randomly divided into groups taking several different sleeping medications in several doses to determine which combinations—if any—are most effective. To better ensure accurate results, one group of participants will be taking a placebo, a sugar pill designed to look like a drug but which produces no effect.

Jet lag is the daytime drowsiness and nighttime insomnia caused by a major disruption in the sleep-wake cycle, such as occurs when flying across many time zones.

An antidote for this condition would be extremely important to such persons as government officials or businessmen who must conduct critical business or negotiations soon after arriving in a distant time zone, or to pilots or other airline personnel who must react quickly and function effectively despite major sleep-wake pattern disruptions.

The current research follows up results published in the June 15 of Science magazine which said that judicious use of short-acting sleeping pills works as an effective treatment for jet lag.

Seidel said that study, conducted jointly with Henry Ford Hospital in Detroit, demonstrated that a full eight-hour sleep period is capable of overriding the body's natural sleep-wake cycle, and can restore alertness in a person forced to be awake when normally asleep.

That same study also showed that long-acting sleeping medications—those which continue to act after the night is over—actually increased the daytime drowsiness).

-more-

Aug. 21, 1984

But the earlier study was conducted in a laboratory and only simulated jet lag by temporarily altering the volunteer's sleep cycle. Now, the researchers want to actually test what they've learned in a "real life" situation by studying volunteers who have traveled half way round the world.

Seidel said volunteers must be between 21 and 59 years old. They must have no problem sleeping well at home and must not have done shift work affecting their sleep cycle less than three months before the flight

All participants must have spent the last 21 days in the Pacific time zone. Starting 14 days before departure, volunteers will begin filling out forms describing their mood twice each day. This, said Seidel, will help researchers compare the volunteers' condition with what they encounter after the flight. The volunteers will also visit a physician at the Stanford Sleep Disorders Clinic for an interview.

Travel plans must meet certain criteria. Flights to either Tokyo (or its time zone) or London must have no more than five hours layover at an intermediate airport.

Participants, said Seidel, must spend at least three days after arrival overseas in either London or Tokyo (or those cities' time zone) and be willing to take the pills for three days and continue to document their moods in writing during this period.

Volunteers must agree to pass on the coffee, tea or alcoholic beverages offered on the flight. Abstention from alcohol and caffeinated beverages runs from the day of departure through 12 hours after the last pill is taken, Seidel said.

Participants will be given a suggested sleep schedule for the first three 24-hour periods after arrival overseas.

Seidel said potential volunteers might include vacationers traveling on a limited budget who might benefit from the money, as well as persons intellectually curious about participating in an experiment.

"We are also hoping that people will be willing to help with an experiment which might help us find an antidote to jet lag," Seidel said. "Anyone who has ever had to travel through multiple time zones and then function effectively on subsequent days would, I think, appreciate the benefits of treatment for the drowsiness and disorientation which often accompany jet lag," he added.

For further information about participating, contact Sue Cohen at the Sleep Disorders Center, (415) 325-4697.

CHAPLAIN TRAINEES SERVE PATIENTS' SPIRITUAL NEEDS

STANFORD—

In the often science-dominated world of high technology medicine, Bethann McIntosh, Cindi Donald Burklo and Sara Armin have a different mission—to bring hope even to situations where the three chaplain trainees know there are no simple answers.

"It always seems so lacking in purpose when a child dies," said McIntosh, who will soon wind up a year's internship in Stanford University Medical Center's trainee program. Helping patients and their families at affiliated Children's Hospital at Stanford (CHAS) connect with whatever restores their faith in life can be a real challenge for someone like herself, who sees children dying from such illnesses as cystic fibrosis or leukemia.

To salvage meaning, McIntosh, a Congregational minister and graduate of the Pacific School of Religion in Berkeley, tries to tune into and build upon whatever belief system the parents and children themselves share.

"Part of being a chaplain means talking to God. I call that prayer," McIntosh recently wrote in a CHAS newsletter. "But, it also means talking to *people*, and listening and sharing and caring and praying with people—people who are feeling hurt and angry and afraid and confused; people who are having doubts and wondering if there really is a God; people who are feeling separated from God and abandoned."

Burklo, working mostly with dying cancer patients, said she's found in them an attitude, trust, and appreciation in life that she wishes more people could discover before being faced with death.

The Congregational minister (of the United Church of Christ) chose to work with cancer patients at the medical center because, she said, "There's lots of fear surrounding cancer, and so many different reactions to it. I felt it was important to help people explore it and gather their resources."

The "very special people" Burklo meets are exemplified by one patient who's had cancer for 15 years, is terminally ill, and who "really trusts herself." Burklo said this woman felt like living alone for awhile, so she camped out in a tent under a tree for an entire season.

Armin, based at the pediatrics unit of Stanford Hospital, believes her presence and spiritual attention to families in pain can be a source of healing, although some want simply to know the church's stand on an ethical issue such as terminating life support. The Methodist minister who is also trained in psychology told the mother of a 17-year-old terminal patient who wanted to be allowed to die that the church would not condemn her for ending his suffering.

One long-term encounter was with a young dying boy's parents who told Armin, "Even if we've only had Eric 21 months it's been worth it for all the love he's brought us."

"I think crises like these can be spiritual turning points for people," Armin said. "The eternal question of 'Why me?' can lead to greater faith or, by contrast, a loss of faith. I saw Eric's parents transform their entire attitude toward life—they became able to see clearly the triviality of most material and other things they used to care about."

2-2-2

McIntosh, Burklo and Armin have served as Stanford University Hospital's first chaplain trainees in a national program certified by the American Association for Clinical Pastoral Education. The program makes it possible for qualified individuals to learn about the chaplaincy's role in a hospital setting, said the Rev. Francis Geer, who, as one of three full-time chaplains at Stanford Hospital, served as supervisor to the trainees. (Geer recently left Stanford for a position in Boston. During the transition period until a successor is found, the Rev. Sharon Thornton is serving as trainee supervisor.)

"This program exists at many hospitals all over the country, many of which are religious or community run," noted the Rev. Ernie Young (currently on sabbatical), a Methodist and director of the chaplaincy service at Stanford Hospital. "The nice thing about having it at a teaching hospital such as Stanford is that there are enormous learning resources, as well as the presence of many housestaff at roughly similar stages in their careers as our trainees—this provides a companionship, zeal, and mutual understanding that wouldn't otherwise exist."

At various stages of ordination and representing different denominations, trainees should realistically reflect the diversity of belief systems found among hospital patients and families, said Young.

"Unlike other ministers, hospital chaplains must be able to respond to people of all denominations," although rabbis and other religious leaders not currently represented in the program are available on-call in the community, Young said.

The first year's trainees were accepted into the program because, among other criteria, "these people have been through things in their personal lives which equip them to better help others," Young said. He added that the trainees have interacted not only with hospital staff, but also with medical students, "for the mutual learning and enrichment of both." For example, Young teaches a course at the medical school on medical ethics, which the trainees attended in addition to their other classes.

Hospital chaplains may perform such services as weddings, baptisms, sacrament of the sick, and the reading of scripture.

However, as Young explained: "This program allows us to place someone on a particular unit for an extended period, which eventually leads to his or her becoming an integral member of the health care team. This is something our permanent staff can never do," he said, "because most of our work involves running around from crisis to crisis."

"Sara found she spent much initial time just getting to know the many different staff and professional people on the unit, and letting them get to know her, so they could develop a well-organized team approach to patient care," Geer added.

Funding for the training program came from a variety of sources, including a gift from the Charis Fund of Portola Valley; an anonymous donor; and a gift from Children's Hospital at Stanford. Trainees pay tuition to the program.

Stipends are $8,000 a year per trainee, Young said. "While many institutions don't give their trainees stipends," he said, "we are accepting donations for this purpose, since Stanford is in a high-cost area."

A special fund was set up for chaplaincy training program donations, which can be sent to: Chaplaincy Service, Room C112A, Stanford University Hospital, Stanford, CA 94305.

PARAMEDIC TRAINEES EARN CREDIT FROM FOOTHILL COLLEGE

STANFORD—

Students enrolled in Stanford University Hospital's Paramedic Education program may now earn credit from Foothill College, SUH and the Los Altos Hills-based community college have announced.

Under the recently established cooperative arrangement with Foothill College, graduates will be eligible to receive credit leading to an Associate Degree and all benefits and privileges of students registered at the community college. Graduates are also prepared to enter the county certification process required for employement.

The Pre-hospital Care Program is currently the only Emergency Medical Technician-Paramedic program operating in the Bay Area. In more than 1,000 hours of instruction and practical on-the-job training, students in the 10-year-old program have learned to make the the rapid, lifesaving decisions needed to care for trauma and emergency victims enroute to a hospital, said Dr. Michael Eliastam, SUH director of emergency services and acting chief of staff.

Eliastam said the new arrangement allowing community college credit, "puts the student on a career track offering maximum options and flexibility. Paramedic work is demanding and exciting. Now these challenges and experiences can be banked toward future academic and career enhancement if the student chooses."

Program Coordinator Sandra Rehmar, R.N., M.S., said the program has a fulltime six-month course or a parttime one-year course. Students wishing an associate degree must attend college the equivalent of two years full time, including the paramedic portion of training.

Certified paramedics communicate by radio with hospital-based physicians and nurses to provide a sophisticated level of care to emergency patients before they reach the hospital. In addition to first aid procedures performed by emergency personnel with less training, paramedics may administer emergency drugs and perform such invasive procedures as inserting a breathing tube into the trachea under the radio-directed supervison of a physician or specially trained nurse.

Classes are held at Foothill College's new Middlefield Road Campus in Palo Alto. Clinical training takes place at SUH and other Bay Area hospitals.

Program details and prerequisite information is available through the Middlefield Campus, 4000 Middlefield Road, room B-7, Palo Alto, CA 94301. For further information, phone (415) 497-6017.

SUH BUDGET RETAINS CURRENT RATES FOR COMMON SERVICES

STANFORD—

Stanford University Hospital's 1984-85 budget will hold the line on daily care rates for nearly half of the approximately 20,000 patients admitted annually, the Board of Hospital Directors has decided.

However, patients requiring the highest levels of nursing and technical care will be paying more for the time they require these services after Sept. 1, bringing the average daily care rate increase to 8.9 per cent. Related patient services—such as laboratory fees—will increase an average of 7.9 percent, said David Sakai, director of finance.

The selected increases for certain categories of patients have been structured to create a more accurate "cost for service" pricing structure, said Sakai.

The board approved Thursday (Aug. 9) an operating budget of $184.9 million, an 8.3 percent increase above the 1983-84 expense of $170.7 million, said Sheldon S. King, SUH director and executive vice president.

He said the rise is based in part on expenses associated with a projected 5.6 percent increase in the number of patient days—which will also bring in additional revenues when the new budget takes effect Sept. 1.

King said patient days (calculated by multiplying the number of patients by the days they stayed in the hospital) are expected to rise to a more normal level after two years of decline for a variety of economic factors.

King said the remainder of the rate increase, required to meet the demands of general inflation and other increased costs, was "smaller than it might have been otherwise, because the hospital has been able to reduce $4.8 million from the current budget through a variety of cost containment measures."

Daily care rates which will stay at current levels include obstetric services, and the daily rates for a category of surgical and medical patients requiring less than six hours daily of nursing care. Those patients requiring intern and resident care will pay the present rate of $384 per day after Sept. 1 for a semi-private room.

No rate increase is being put into effect for comparable patients in a ward, $362 per day, or in a private room, $438 daily.

The major change in rate structures includes addition of a new rate category—$548 per day—for medical/surgical patients who receive 6-8 hours of nursing care per day. Currently, these patients are charged the same rate as patients requiring six hours or less of nursing.

Another typical room rate is $245 per day—up from $225—for the care of healthy newborn infants.

Intensive care room rates will be increased 8.9 percent, with the most commonly charged rate going from $1,338 to $1,457. Psychiatry inpatient charges will rise from $426 to $464 daily.

A total of $6.1 million has been earmarked for equipment additions and other capital improvements. Projects include radiographic/fluoroscopic equipment, $488,000; linear accelerator construction, $350,000; nuclear magnetic resonance construction, $350,000; renovation for trauma center and X-ray room, $288,000; and a computerized Medicare Prospective Payment System, $250,000.

PERINATAL RISK: CONFERENCE SCHEDULED

STANFORD—

"Care of the Perinatal Patient at Risk: Conception to Infancy" is the topic of the sixth annual education program of the Mid-Coastal California Perinatal Outreach Program (MCCPOP), sponsored jointly by Stanford's and Santa Clara Valley Medical Center's departments of gynecology and obstetrics and pediatrics.

The program, beginning Sept. 5 in Faber Auditorium of Children's Hospital at Stanford, will take five consecutive Wednesdays to focus respectively on conception, antepartum (before childbirth), intrapartum (during childbirth), neonate at risk, and infancy and beyond.

The series has been designed to provide a theoretical and practical basis for physicians, nurses, and other health care professionals who care for high-risk perinatal patients, said registered nurse Cecele Quaintance, program director of MCCPOP.

Topics include "Infertility," "Cost of Perinatal Care," "Amniocentesis and Genetic Counseling," "Diabetes and Pregnancy: The New Insulins and Glucagon," "The Process of Maternal Referral and Transport," "The Use of Intrapartum Ultrasound," "Early Care of the Infant with Cardiac Anomalies," "Infants at Risk for S.I.D.S.," and "Decision Making and the Defective Newborn," among others.

Faculty from Stanford will be joined by nutritionists, administrators, and specialists from Santa Clara Valley, other hospitals, and private practice.

MCCPOP has developed educational programs throughout an eight-county region (San Mateo, Santa Clara, San Benito, San Luis Obispo, Monterey, Santa Cruz, Stanislaus and Alameda). The program includes a perinatal resource center, a genetic counseling center, and a birth defects center, as well as providing emergency consultation and transport, perinatal nursing internships, and intensive care nursery internships.

A registration fee will be charged participants of the upcoming conference, for one day, several days, or the entire program, with a lower charge for those registering by Aug. 20. The conference has been approved for continuing education credit. For further information and registration materials, call Kim Leadon at (415) 497-5763.

JAMISON NAMED ACTING CHAIRMAN OF MEDICINE

STANFORD—

Dr. Rex Jamison, professor of medicine and physiology and chief of the division of nephrology at Stanford University Medical Center, has been appointed acting chairman of the department of medicine, announced Dr. Lawrence Crowley, vice president for medical affairs.

Jamison was also named acting chief of the medical service of Stanford University Hospital. Both appointments were effective Aug. 1.

He replaces Dr. Kenneth Melmon, professor of medicine, who in June resigned both administrative positions effective July 31.

Jamison has published extensively, best known for his research in the area of renal physiology. He's played a key role in the creation and operation of the hemodialysis center at Stanford. More recently, he announced reactivation of the medical center's kidney transplantation program.

A graduate of Harvard Medical School, Jamison, 51, was a Rhodes Scholar, a Markle Scholar, and a Guggenheim Fellow, among other honors. He joined the Stanford faculty in 1971, after holding posts at the Washington University School of Medicine, The Jewish Hospital of St. Louis, and the National Institutes of Health.

At Stanford, he has been an undergraduate advisor, chairman of the hospital's Dialysis and Transplant Committee, member of the medical school's Basic Sciences Curriculum Committee, member of the university's Senate of the Academic Council, and active faculty participant in other capacities within the university and department of medicine.

Jamison belongs to the American Physiological Society, the American Society for Clinical Investigation, the California Academy of Medicine, and the Western Association of Physicians, among other professional organizations. This year he serves as chairman of the program committee of the American Society of Nephrology. He has served on numerous editorial and advisory boards.

NEW DIRECTOR FOR STANFORD'S LAB ANIMAL MEDICINE DIVISION

STANFORD—

Dr. Thomas Hamm has been appointed director of the division of laboratory animal medicine at Stanford University Medical School, announced David Mendelow, associate dean.

Hamm, whose post became effective July 23, came to Stanford from North Carolina, where he headed the department of general and biochemical toxicology at the Chemical Industry Institute of Toxcology in Research Triangle Park. His appointment marks the first time a veterinarian will head the division.

Hamm succeeds Dr. James Dewson, who is planning to leave Stanford University to pursue other career interests.

In his new position, Hamm will be in charge of the medical school's animal laboratories, which will be moving to a new facility — currently being built underground adjacent to the medical center — in January 1985. About 75 percent of the medical school's principal investigators make use of laboratory animals in their research studies. On the average, about 8,000 animals from about 30 different species are accomodated within the division's facilities.

Under the direction of Hamm, Mendelow said, the division will increase its support of the needs of medical school researchers by, among other activities, recruiting veterinarians with specific areas of expertise. Longer range plans, he added, include establishing a post-graduate training program for research veterinarians.

Hamm received a doctorate degree of veterinary medicine from Colorado State University and a Ph.D. in comparative pathology from Bowman Gray Medical School in North Carolina.

Prior to his four year stint at the toxicology institute, Hamm served as an expert consultant and acting chief of the toxicology branch of the carcinogenesis testing program at the National Cancer Institute from 1978-80, and as assistant professor in the pathology department at University of Colorado Medical Center from 1975-78. Hamm has trained in the use of animal models for atherosclerosis research in addition to his training in toxicology.

Hamm can be reached at 497-3876.

WEIGHT CONTROL PROGRAM STARTS NEXT MONTH AT STANFORD HOSPITAL

STANFORD—

An eight-week course on weight control is scheduled Sept. 18 to Nov. 6 at Stanford University Hospital.

The course, which is open to the public, will be held Tuesday evenings in the north cafeteria of the hospital.

Highlights of the program, entitled "An Enlightening Experience," include a personalized weight-loss plan, low-calorie cooking demonstrations and recipes, menu planning, and tips on dining out wisely. Guest speakers will discuss stress reduction, behavior modification techniques, and exercise.

Kristine Birge and Patricia Kearney, registered dietitians from the hospital's department of dietetics, will conduct classes. The fee is $300, with a $50 refund if a weight goal is met.

The registration deadline is Sept. 4, and early registration is advised. Enrollment is limited to 20. Another session is planned for Jan 8.

For more information, call Birge at (415) 497-5440.

FOR IMMEDIATE RELEASE

HEART ASSIST DEVICE APPROVED FOR CLINICAL TRIALS

STANFORD—

A fist-sized electronically controlled device that can temporarily help a failing heart pump blood through the body is ready to be implanted on an emergency basis in patients at Stanford University Medical Center.

The Food and Drug Administration (FDA) last month granted approval for human testing of the device, which has been under development for more than a decade by Stanford physicians and scientists at Novacor Medical Research Corporation of Oakland.

Last week, an operating room rehearsal prepared physicians, nurses and other personnel for the first patient.

The operation will be the first implantation of a heart assist device performed at Stanford, although nationwide during the last few years more than 200 patients have been outfitted with various temporary devices that supplement the heart's pumping action.

The Novacor device, to be implanted in patients on a temporary basis, is a forerunner to a totally implantable pump with a portable power supply that could bolster a patient's own heart on a longterm basis, said Dr. Philip Oyer, associate professor of cardiovascular surgery.

Oyer added that although development of the longterm implant is still under way, more than 10 years of laboratory and animal testing paved the way for the FDA's recent approval of the temporary device for human trials.

Stanford and Novacor have permission to place the device in up to 20 patients.

Patients who take a sudden turn for the worse while waiting for a heart transplant, or those whose hearts unexpectedly fail during open-heart surgery but are thought to have a good chance of recovering if their own hearts are given several weeks of rest, are among the potential candidates for implantation, Oyer said. The device has not been approved for patients who are in the process of having a heart attack, he added.

The temporary device will be left in place for up to two weeks, Oyer said, until the patient's own heart is strong enough to work on its own again.

8-1-84 -more-

The device is hooked to the failing heart and sits below it in the abdominal region. It draws blood from the patient's own weakened organ and pumps the blood around the body, taking most of the burden off the sick heart muscle and giving it a rest.

"This current device is a major step toward a totally implantable assist system that could supplement a patient's own heart for several years," Oyer said. "However this totally implantable system is still under development and remains several years away from clinical use," Oyer added.

The implantation of this first generation mechanical device by Stanford cardiovascular surgeons known worldwide for their pioneering heart transplantation program, will not represent a shift in focus from transplantation, Oyer said.

"They are complementary technologies. There are some patients who cannot receive transplants for a variety of reasons. For these patients, the longterm device under development might be useful," Oyer said. But, "for the foreseeable future, heart transplantation remains the best option for patients with endstage heart disease."

Shumway, cardiovascular surgery department chairman, added, "When there is a chance that a damaged heart can recover with time, a temporary assist device would be preferable to transplantation."

The device—technically known as a left ventricular assist device (LVAD)—takes over for the left ventricle, the muscular workhorse heart chamber that pumps blood into the body's 60,000-mile network of blood vessels.

The plastic pump encased in a metal housing will be installed in the patient's abdominal region. Blood is shunted to the pump through a dacron conduit from the left ventricle. The pump ejects blood back into the circulatory system through another dacron tube leading to the aorta.

The LVAD is linked by a cable passing through the patient's abdominal wall to a bedside control console that provides power. The console also holds computerized equipment that monitors the heart's beating pattern and directs the pump to beat in synchrony with the patient's natural cardiac rhythm.

The new pump has been under development since 1972 by Stanford and Novacor researchers. Dr. Peer Portner, chief executive officer of Novacor, has directed engineering research and development of the device, which is called the Pulsemaker Heart Assist System by its manufacturer. Portner is also consulting associate professor of cardiovascular surgery at Stanford.

The Novacor device incorporates several design improvements over previous LVADs, Oyer said. The most important of these is that unlike the prevalent pneumatic systems—whose mechanical action depends on bursts of compressed air fired through a tube that enters the patient's body—this pump is electronically controlled and activated.

In the future system currently under development and probably available in about three years, the power/monitor computer will be miniaturized to a size that can be completely implanted inside the body. A belt worn around the waist will be capable of transmitting power through the intact skin to the implanted components of the permanent LVAD.

-more-

The belt transformer will do away with the need for wires that pierce the skin, which are a potential source of infection, Oyer said.

Like an artificial heart, an LVAD is installed at the present time only in patients for whom more conventional therapy has been ineffective and who would die without the mechanical aid, Oyer explained. Current LVADs are primarily for patients who need to be tided over a critical period of heart failure, he added, and only for patients whose own diseased hearts are likely to recover during the few days or weeks the device remains in place.

This includes patients having recent heart surgery who are in cardiogenic shock and whose own hearts cannot provide the blood pressure needed to maintain circulation, and open-heart surgery patients who cannot be weaned from the heart-lung bypass machine immediately following an operation.

An LVAD might also bridge the gap for a potential heart transplant patient whose own heart cannot hold out during the wait for a suitable donor organ, Oyer said.

Oyer estimated that Stanford may perform between five and 10 implantations in the next year. Clinical trials could expand to other medical centers within a year or two, he added, if the device proves effective.

In a study for Novacor, the consulting firm SRI International estimates that more than 100,000 patients today could potentially benefit from a permanently implantable version of the LVAD.

According to Oyer, survival rates were poor with LVADs tested in the 1970s; fewer than 25 percent of patients survived long enough to be weaned from the pump and discharged from the hospital. More recently, survival rates for patients with temporary LVADs have increased to nearly 50 percent, he noted.

Other centers that have tested LVADs include Pennsylvania State University in Hershey, Washington University in St. Louis, Boston Children's Hospital, the Cleveland Clinic, Presbyterian Medical Center in San Francisco, and the Texas Heart Institute, Oyer said.

The Stanford/Novacor device enters clinical testing after more than a decade of laboratory experimentation. It has been tested in more than 100 calves, some of which lived with the device for as long as six months, Oyer reported. Further development and animal testing is necessary before the fully implantable LVAD can be considered in humans, Oyer said, to prove that the pump and its components can work continuously for a duration of several years. These studies on the longterm LVAD will be carried out over the next three years, he said.

Although the patient will be tethered by cords to the external console with the present temporary device, the limited mobility is no different from being dependent on a respirator or other life-sustaining device for a few weeks, Oyer said.

The totally implantable device, once it becomes available, will include a small rechargeable battery pack allowing the patient to become untethered. But the patient will still need to be near an external electrical power source such as a wall outlet or battery, Oyer said. An implanted battery will be designed into the system to provide up to an hour or two of device operation free of any external electrical power.

"It is primarily because of this dependency on an external power source for all patients with mechanical cardiac support devices of any kind, that we believe cardiac transplantation, which allows complete freedom and mobility, will offer the better quality of life for the foreseeable future," Oyer said.

The pump itself is straightforward. Two pusher plates that form the device's opposite sides move together to squeeze blood out of the chamber. As blood refills the internal sac, the plates pivot apart.

The pump's rhythm is controlled by a microprocessor that tells it when to beat, and how forcefully. In most cases, it is programmed to beat in synchrony with the patient's own rhythm, Oyer said, although it also has the capacity to beat at a steady predetermined rate, irrespective of the patient's own heart rate. It can adjust automatically for increased exertion and can beat up to 180 times per minute, a pulse rate achieved during strenuous exercise by an active young adult, he added.

The surgical implantation procedure is relatively simple, Oyer said. The pump and supporting components are installed in the abdominal region below the heart.

While blood is detoured around the heart through a heart-lung bypass machine, incisions are made in the heart and the aorta, the major artery leading from it. Through a small puncture made at the bottom of the left ventricle, a tube is placed so that blood can flow into the pump. Another tube leads from the pump to the aorta, returning blood to the circulatory system. These tubes are plugged but left in place when the LVAD is removed.

Animal tests have revealed some medical complications that could develop with LVAD use, Oyer said. In short-term use, there is a small possibility that blood clots could form within the device and travel to other parts of the body, such as the brain, causing stroke. There is also a small risk that blood components could become damaged, causing bleeding problems, he added. And there is a slight chance of mechanical or electrical failure in the LVAD itself, he said.

Long term studies in animals point to added potential complications including a buildup of calcium deposits on the device's valves, and blockage of the dacron tubes due to layering and growth of cells on the inner surfaces. These complications may not occur in adult humans, Oyer said, but might be unique to the young, growing animals tested, whose metabolism is different from adults. Further testing in adult animals—particularly in sheep whose hearts are closer in size to humans—is ongoing, he added.

Some other drawbacks may crop up for patients on the LVAD, Oyer added. Some individuals could be disturbed by the pump's vibration and noise generated by the pump as it empties and fills, he said. But although mobility is limited by the external console in the current device, freedom of movement will become much greater when the belt model becomes available, he observed.

HOME GLUCOSE MONITORING ON DISPLAY\c

STANFORD --

The diabetes and metabolism clinic at Stanford University Medical Center is presenting educational sessions Thursday, Oct. 4, to inform the public of methods and equipment used in home glucose monitoring.

The agenda will include visits by sales representatives, and question and answer periods following the lectures, said Dr. Fredric Kraemer, assistant professor of medicine and director of the clinic.

The 30-minute class, to be held at 10 and again at 11 a.m. in room A160, is open free to the public. To reserve a seat, call Ingrid Gallo, at (415) 497-5947.

VOLUNTEERS SOUGHT FOR SMOKING CESSATION STUDY

STANFORD --

Researchers at Stanford University Medical Center are seeking about 100 volunters to participate in a study investigating how the effects of nicotine chewing gum might help people to quit smoking.

Smokers who wish to quit with the aid of Nicorette, a nicotine chewing gum available by prescription, can receive up to a three month supply of gum in exchange for being in the research program. Participants will attend four weekly meetings at Stanford where they will fill out questionnaires and discuss the project, said Andrew Gottlieb, a graduate student conducting the research under the auspices of the behavioral medicine clinic.

Nicorette is designed to help smokers kick their dependence on cigarettes without suffering from withdrawal symptoms, such as irritability, hunger, anxiety, depression or boredom, the researcher said. Each piece of gum contains about the same amount of nicotine as one cigarette but is absorbed more slowly. Smokers who have quit chew between eight to 15 pieces of gum a day whenever they experience a craving for a cigarette.

``We are attempting to measure the physical -- through the participants own reports -- and psychological symptoms of persons during the critical first few weeks of quitting smoking,'' Gottlieb said. Some of the participants will be receiving a placebo initially but will be given the gum if they choose after several weeks, he added.

``A number of studies have suggested that using Nicorette gum can double the quit rate,'' said Gottlieb. ``Other studies show that Nicorette reduces the severity of withdrawal symptoms.''

The study is being funded by Merrill Dow Pharmaceuticals Inc., manufacturer of Nicorette.

For information on how to participate, call only after 5 p.m., Oct. 1 through 5, (415) 497-5867.

FOR IMMEDIATE RELEASE

ANNIVERSARY AT MEDICAL CENTER BEGINS WITH OCT. 12 CELEBRATION

STANFORD--

Opening ceremonies for Stanford University Medical Center's 25th anniversary celebration have been scheduled for Oct. 12 in Sherman Fairchild Auditorium.

Guest speakers for the all-day public event include Paul G. Rogers, former chairman of the congressional House Subcommittee on Health and the Environment, who will discuss "The Academic Medical Center as a National Resource." Rogers, a Florida Democrat, currently practices law in Washington, D.C.

Lawrence G. Crowley, vice president for medical affairs, said the object of the anniversary celebration is to rededicate the institution to the principles established at the time the medical school was brought to the Stanford campus in 1959 after 51 years in San Francisco. The principles link medical education and patient treatment with the total resources of the university and the surrounding communities.

Throughout the coming year, a variety of educational events will be scheduled in honor of the consolidation.

The morning program, starting at 10 a.m., includes welcoming speeches by Lawrence G. Crowley, vice president for medical affairs and Donald Kennedy, president of the university. "There's No Hope for the Satisfied Man" is the topic of a speech by Robert H. Alway, professor of pediatrics, emeritus, and dean of the Medical School from 1957 to 1964.

Also speaking will be Hugh O. McDevitt, professor of medicine and microbiology, and a slide program depicting the Medical Center will be shown.

"Song of the Vowels," a Jacques Lipchitz sculpture honoring the memory of Stanford cancer pioneer Henry S. Kaplan, will be formally dedicated in midday ceremonies. Kaplan, a professor of radiology, died earlier this year.

Afternoon lectures will begin with Rogers at 2 p.m. and will also feature "The Heart of the Matter" by heart transplant pioneer Norman E. Shumway, professor and chairman of the department of cardiovascular surgery; and "Responding to New Challenges: The Future of Stanford University Medical Center," by Victor Fuchs, professor of economics and of family, community and preventive medicine.

Since 1959, the goals of the medical center, summarized in a statement by Crowley, have included bringing together under one roof a full-time faculty in the basic and clinical sciences to advance medical knowledge.

Other goals include access to academic resources on the rest of the campus, the opportunity to apply basic research findings in a nearby clinical setting, and to "provide exemplary patient care in a teaching hospital environment both to the citizens of Palo Alto and nearby communities and to those patients referred for specialized care."

SMASHING LECTURES PLANNED AT MEDICAL CENTER

STANFORD—

Next week marks the opening of the fall 1984 S * M * A * S * H lecture lineup at the Stanford University School of Medicine.

The lecture series — whose full name is "Stanford Medical and Scientific Highlights" — was initiated in 1980 by the medical school's Faculty Senate, which now cosponsors it with the Stanford Medical Students Association.

The season's lectures are as follows:

- Oct. 5: "AIDS, Toxoplasma, and Tumors," with Dr. Frances Conley, associate professor of neurosurgery;
- Oct. 19: "Muscle Building and Muscle Bound: Activation and Expression of Muscle Genes," with Dr. Helen Blau, assistant professor of pharmacology;
- Nov. 2: "Transvection, Amplification, and Cloning of Genes," with Dr. Leonard Herzenberg, professor of genetics;
- Nov. 16: "DNA Polymorphisms in Humans," with Dr. Luigi Cavalli-Sforza, professor of genetics;
- Nov. 30: "How Genes Control Development," with Dr. David Hogness, professor of biochemistry.

The SMASH organizing committee hopes to encourage a wide exchange of ideas, and to provide a forum by which the community may be informed of significant medical research and developments at Stanford. The Friday talks are geared toward all those with basic scientific understanding.

The season's presentations will take place in the Fairchild Auditorium. Lectures will start at 4:30 p.m. and be followed by TGIF gatherings.

COLD SORE SUFFERERS SOUGHT BY RESEARCHERS

STANFORD—

Persons suffering from cold sores, known medically as recurrent herpes, are being sought by Stanford researchers for an experiment which could lead to a vaccine against this common malady.

Dr. John Torseth of the division of infectious diseases, said about 30 to 40 volunteers will be asked to make two visits to Stanford Medical Center for blood drawing and a brief examination. Participants will be paid $10 per visit and will have priority for receiving the vaccine when it is developed to the point of human tests, Torseth said.

The vaccine has been produced using recombinant DNA techniques, a method of altering natural biological substances to new forms. Earlier attempts to produce a vaccine using more conventional means were risky because impurities in the process could potentially contaminate recipients, Torseth said.

Torseth said only persons with herpes on the face or lips are eligible to participate in the study. Virus cultures will be obtained to verify what type of virus each patient has.

For further information or to volunteer, call Torseth at (415) 497-5715 from 9 a.m. to 5 p.m. If no answer, call (415) 497-5909.

VOLUNTEERS SOUGHT FOR STUDY ON WEIGHTLESSNESS AND THE KIDNEY

STANFORD—

Healthy male volunteers aged 20 to 55 and heart transplant recipients are helping researchers learn how and possibly why weightlessness enountered in space flight changes kidney function.

Dr. Stephen Tomlanovich, a fellow in nephrology at Stanford University Medical Center, said the study is a joint project with NASA-Ames Research Center of Mountain View, where scientists had noticed that astronauts encountering weightlessness tended to eliminate fluids more readily than normal.

To simulate space flight for the current experiment, about six men will be immersed in warm water for about three hours. Several blood samples will be drawn to measure how kidney function has changed in response to the simulated weightlessness encountered in the tub.

Weightlessness or immersion causes more blood to flow into the heart, resulting in temporary enlargement of that organ. When this occurs, nerve and hormonal signals tell the kidneys to help reduce the pressure caused by the swelling in the body. The kidneys respond by triggering urination.

The heart transplant patients offer a unique study opportunity, Tomlanovich said, because they have no nerves connected to their implanted hearts. Therefore, their response to water immersion should be quite different from other people. This, he said, should offer insight about the role of the nervous system in kidney function.

The information, he said, could ultimately be useful to the space program if methods of counteracting the effect of weightlessness on the kidneys could be developed. The excess urination is potentially hazardous, Tomlanovich said, because it removes needed body fluids.

The normal, or control, volunteeers, will be paid $50 for spending about three hours in the tub and about three hours more undergoing tests, the researcher said.

Persons interested in volunteering should contact Tomlanovich or Dr. Bryan Myers, associate professor of medicine (nephrology) and the principal investigator, at (415) 497-6248, weekdays between 8 a.m. and 5 p.m.

DRUG BLOCKS PARKINSONISM IN ANIMAL TESTS

STANFORD—

A drug that shows promise in slowing the course of Parkinson's disease has been successfully tested in animals by a Stanford University neurologist and his research team.

In the Sept. 28 issue of *Science* magazine, the scientists reported that the drug, pargyline, prevented Parkinson's disease symptoms from developing in monkeys that had been given a chemical that causes a severe form of the disorder.

"We have shown that pargyline blocks experimentally induced parkinsonism in animals," said Dr. J. William Langston, assistant professor of neurology at Stanford Univeristy School of Medicine who carried out the research at Santa Clara Valley Medical Center and the Institute for Medical Research in San Jose.

"The exciting possibility—and it's still only a possibility—is that this drug might also block progression of Parkinson's disease in humans," Langston said in an interview. The drug currently is in use as a treatment for high blood pressure.

"Actually blocking or slowing Parkinson's disease, rather than controlling its symptoms, would be a whole new concept in treatment of progressive neurodegenerative diseases," Langston said.

Parkinson's disease is a neuromuscular disorder characterized by stooped posture, rigid movements, shuffling gait, involuntary tremors and loss of facial expression. It is estimated to afflict approximately half a million people in the U.S., including one person in 40 older than 70, Langston said.

It is caused by death of cells in the part of the brain called the substantia nigra. These cells produce a vital brain chemical called dopamine, thought to be important in control of movement.

Treatment with the drug L-dopa, which the brain can use to make dopamine, controls symptoms so that most patients can lead fairly normal lives, Langston said. But L-dopa has undesirable side effects and eventually loses its effectiveness enabling the disease to progressively worsen, he explained.

Langston said that his team's studies, along with other work in the field, provide enough evidence of pargyline's effectiveness to begin testing similar drugs in people with Parkinson's disease.

Langston's colleagues in the research are Ian Irwin, a research chemist at the Institute for Medical Research (IMR), Dr. Elizabeth Langston, research associate at IMR, and Dr. Lysia Forno, Stanford professor of clinical neuropathology at the Palo Alto Veterans Administration Medical Center.

Pargyline is one of a class of prescription drugs called monoamine oxidase (MAO) inhibitors, Langston said. Another MAO inhibitor, called depranyl, has been used for several years in Europe to supplement L-dopa treatment of Parkinson's disease patients, he noted. A recent review of those patients' disease histories suggests that depranyl not only helped relieve symptoms but may have helped slow the course of the disease.

Langston and his colleagues plan to begin controlled studies of an MAO inhibitor in Parkinson's disease patients in the near future, he said.

Langston said that if MAO inhibitors prove to work in people as they have in monkeys, the drugs could slow or possibly prevent brain cell damage from becoming severe. "Parkinson's disease worsens very slowly," he explained, "so we can catch the disease early when the patient could go on to lead a fairly normal life."

Rapid progress in understanding Parkinson's disease followed a 1983 discovery by Langston and colleagues that a contaminant of synthetic heroin, known as MPTP, can cause permanent Parkinson-like symptoms in people (or monkeys) who consume the chemical. This discovery opened up new ways of studying the brain disease in animals, and new clues to the possible causes of the condition.

Research now suggests that pargyline may block MPTP from inducing parkinsonism by halting a chemical reaction that converts MPTP into more harmful substances in the brain. It is one of these more harmful substances that might actually kill the brain cells of the substantia nigra, Langston explained.

It is clear that MPTP itself is not toxic, Langston reported, because large quantities of this chemical were found in brain cells of the pargyline-treated monkeys, all of whom remained healthy and free of parkinsonism.

Langston's research on Parkinson's disease has been funded by The Retirement Research Foundation of Illinois, the Institute for Medical Research, Santa Clara Valley Medical Center, and the Veterans Administration Medical Research Program.

FOR IMMEDIATE RELEASE

PATIENT ON CARDIAC ASSIST DEVICE RECEIVES TRANSPLANT

STANFORD—

The implantable cardiac assist device which sustained a critically ill patient for more than a week was removed Thursday night (Sept. 13) in an operation which also gave the patient the new heart he needed for longer term survival, doctors said.

Dr. Philip E. Oyer, associate professor of cardiovascular surgery at Stanford University, said Robert St. Laurent, 51, was reported in critical but stable condition Friday morning at Stanford University Hospital after the six-hour operation which replaced both the left ventricular assist device (LVAD) and the patient's own ailing heart with a healthy new heart.

The operation—which Oyer said went smoothly—marked the first time at Stanford that an LVAD was used to support a patient until a biologic donor heart could be located and implanted. It was also the first time that the Pulsemaker Heart Assist System was implanted into a human patient.

Although about 200 patients have been outfitted with various temporary LVADs, Oyer told a news conference last week that the experimental Pulsemaker seemed to offer the best hope of serving as the nucleus of a future totally implantable portable system, since it was electronically—not pneumaticallly—driven and because it had specifically been engineered for portable use.

The system, unlike most others, minimizes the risk of infection, since the pump is completely implanted except for a single electrical support line into the body, Oyer said.

"We are confident that without the implanted device Mr. St. Laurent would not likely have survived until a suitable donor heart could be located," said Oyer, who headed the team which performed the surgery.

"This first use of the device seems to have been successful because of the effective functioning of a device which may someday offer seriously ill cardiac patients a mobile quality of life," Oyer added.

The surgeon explained that doctors decided to implant the fist-sized LVAD on Sept. 5 after the Ft. Lauderdale, Fla., resident's condition became grave. Efforts had been made earlier to keep St. Laurent alive using an intraaortic ballon pump, an inflatable device inserted into a major artery which by increasing and decreasing air pressure can augment cardiac function about 10 percent. The balloon pump initially improved his condition substantially, but later St. Laurent began to deteriorate and the LVAD was then implanted, Oyer explained.

The LVAD, which took over 100 percent of the workload of the heart's left ventricle (the main pumping chamber), functioned effectively and without complication during the entire eight days, even though the patient remained seriously ill from his longstanding illness, the surgeon said.

In July, the Food and Drug Administration after 14 years of testing in an engineering lab and on animals, approved human testing of the LVAD, manufactured by Novacor Medical Corp. of Oakland.

The pump, encased in plastic, takes over for the left ventricle, the muscular workhorse heart chamber that pumps blood into the body's 60,000-mile network of blood vessels. The device is connected to the failing heart, positioned below it in the abdominal region.

While he was sustained by the implant, St. Laurent had been able to get out of his bed and sit in a chair in the intensive care unit. His assist device was connected by a 14-foot cable to a bedside console which provided power and also contained monitoring equipment.

Within about three years, the functions provided by the monitor should be miniaturized to a size that can be completely implanted inside the body with no external wires piercing the skin, said Peer M. Portner, chief executive officer of Novacor and a consulting associate professor of cardiovascular surgery at Stanford.

St. Laurent had been accepted into Stanford's transplant program on July 6. For at least four years, he had been so ill from hardening of the arteries that he had been unable to work at his job as general manager of a recycling plant. Previous double bypass surgery had failed to correct St. Laurent's problem, and Oyer said that without a transplant the patient had no more than a few months to live.

St. Laurent was Stanford's 313th heart transplant patient since the program began in January 1968.

FOR IMMEDIATE RELEASE

Dr. Bryan Myers and possibly other researchers will meet with reporters at 10:15 a.m., Thursday, Sept.13 in the conference room library of the Cardiovascular Research Building, which is at the intersection of Quarry Road and Blake Wilbur Drive.

STUDY SHOWS LINK BETWEEN TRANSPLANT DRUG AND KIDNEY DAMAGE

STANFORD—

Scientists at Stanford University Medical Center have reported that permanent kidney damage can result from continuous use of a drug credited with dramatically increasing survival rates of organ transplant patients.

The study, published Thursday (Sept. 13) in the *New England Journal of Medicine*, warns that the potential benefits of the drug cyclosporine may be offset in transplant patients by the medication's ability to cause irreversible kidney damage.

But the benefits of cyclosporine might be retained while minimizing the risks to the kidney by modifying its chemical structure or by lowering the dose and shortening the duration of its use after transplantation, said Bryan D. Myers, associate professor of medicine (nephrology), and principal author of the study.

Stanford's own heart transplant program has already modified use of cyclosporine based partly on clinical data leading to the current article, said Dr. Philip E. Oyer, associate professor of cardiovascular surgery and a member of the Stanford transplant team.

Myers said that transplant teams around the nation had suspected cyclosporine might cause damage to the kidneys since about 1978, two years after the drug was first introduced experimentally.

However, he added that studies of the drug's use in kidney transplant patients had not resolved whether kidney damage was being caused by the drug or by the patient's rejection of the donor organ.

In the current study, 79 heart transplant patients whose kidneys were normal at the time of transplant were examined for kidney function during a one-year period following the surgery.

The 32 patients who received cyclosporine to control rejection of the new heart were found to have less effective kidney function several months after transplant than a comparable group of 47 patients who received other anti-rejection drugs.

The extent of adverse symptoms varied among the heart transplant patients on cyclosporine, Myers reported. While some suffered no obvious symptoms of major kidney damage, two of the cyclosporine patients contracted end stage renal disease and had to undergo kidney dialysis.

Myers said the current study shows that some loss of kidney function, observed in 100 percent of the patients studied, could be attributed directly to the cyclosporine, a fungal derivative. He said damage typically took the form of scarring of kidney tissue.

The findings suggest "that any benefit derived from reduced rejection of renal allografts (kidney transplants) may be more than offset over the long term by chronic nephropathy (kidney damage) induced by the cyclosprine therapy itself," the article's authors said.

9-12-84

-more-

However, they noted that use of the drug in low doses and on a short term basis may not lead to irreversible kidney problems.

"It is to be hoped," the authors continued, "that measures will be developed that will widen the margin of safety between the dose of cyclosporine required to achieve effective immunosuppression and the dose likely to cause renal damage."

Co-authors of the article include Jon Ross, acting assistant professor of pathology; Lynn Newton, R.N.; John Luetscher, emeritus professor of endocrinology; and Mark Perlroth, clinical professor of cardiology.

Oyer said that steps have already been taken to reduce the potential danger of kidney damage while retaining high survival rates for heart transplant patients at Stanford.

The current survival rate for heart transplant patients at Stanford is 81 percent for one year, and 73 percent for two years. Before cyclosporine began to be used on all heart transplant patients at Stanford in December 1980, the survival rate was 63 percent for one year, and 56 percent for two years, according to the transplantation program's statistics.

A total of 311 heart transplants have been performed at Stanford since the program began in January 1968, including 200 before cyclosporine became available.

Oyer said dosages of cyclosporine have been reduced in the most recent group of patients, who are receiving the drug in conjunction with azathioprine (Imuran), an older immunosuppressive. Also, a modified version of cyclosporine, offering the possibility of reduced kidney toxicity, is currently being tested in the laboratory, he said.

One patient who suffered serious kidney damage after his transplant about two years ago has been taken off cyclosporine and is reported doing well on azathioprine, while another patient was reported doing well after his cyclosporine was substantially reduced.

Oyer noted that the two patients placed on dialysis subsequently died, although in both cases causes in addition to renal failure were involved, Myers said. Oyer said both of these patients were unusual because unlike other pre-cyclosporine patients who remained on their original immunosuppressive protocol, these two patients were transferred to cyclosporine because the drugs they had taken failed to protect them adequately.

In an editorial appearing in the same *New England Journal* issue, Terry B. Strom and Rolf Loertscher, physicians at Beth Israel Hospital in Boston, said they were "optimistic that a clinical trial can aid in selecting safe protocols that will preserve the dramatic improvements in transplant success."

Strom and Loertscher noted that smaller doses of cyclosporine and/or newer drugs or treatment methods might be used. Both doctors noted the use of lymph node irradiation, which has been reported by Stanford physicians as a promising adjunct to medication in the prevention of rejection in kidney transplant patients.

Cyclosporine, marketed as Sandimmune by Sandoz Chemical Co. of Basel, Switzerland, had been heralded as a major improvement in the treatment of transplant patients. The precise mechanism by which the drug works is uncertain, but it appears to inhibit the action of T-cells, cells of the body's defense system responsible for rejecting foreign tissue.

Researchers have said that cyclosporine's principal advantage over more conventional anti-rejection drugs such as prednisone and azathioprine was its ability to prevent rejection while allowing the body to retain some of its natural ability to fight off infection.

Cyclosporine also made possible combined heart-lung transplantation, because unlike other immunosuppressives which retard the healing process, it allowed healing of the windpipe following surgery.

Cyclosporine is a metabolite of the fungus Trichoderma polysporum and is composed of 11 amino acids hooked together to form a ring.

Funding for the study came from grants from the National Institutes for Health.

FORMER PREMATURE INFANTS GATHER AT HOSPITAL REUNION

STANFORD—

About 500 youngsters who began life struggling for survival in Stanford University Hospital's neonatal intensive care unit are expected to gulp juice, munch food, pet animals and shake hands with clowns at the 2nd Annual Preemie Grad party.

Barb Magee, a registered nurse in the unit and coordinator of this year's reunion, said all youngsters who underwent sustained treatment in the unit have been invited with their parents to the event, scheduled Sept. 16 from 1 to 4 p.m. in the lawn in front of the medical center's Fairchild Auditorium.

Kathleen Palange, clinical nursing coordinator in the unit, said many of the families whose children were treated in the unit developed a closeness with the staff, as well as with other parents in the same situation. The reunion, she said, gives the adults a chance to renew old acquaintances and learn of support group activities.

"Even though as majority of the children are perfectly normal, for the parents it takes a long time to get over the trauma of having a child—in this case a newborn infant—in a critical care situation," she said. Some parents may also have practical difficulties to deal with in caring for a youngster who may come home with continuing medical problems.

Representatives of parent support groups throughout Northern California will be at the reunion to offer advice and the opportunity for membership, Palange said.

In addition to refreshments, clowns, balloons, games and music, entertainment will include a visit by several small animals from Marine World Africa U.S.A, said Palange, who added that the event isn't entirely for children and their families.

She said staff members get a big morale boost in seeing the tiny or sick, struggling events grown into healthy, playful children.

HEART ASSIST DEVICE IMPLANTED IN AILING PATIENT

STANFORD—

A 51-year-old patient was reported in serious but stable condition Thursday (Sept. 6), one day after being implanted with a device that can temporarily help a failing heart pump blood through the body.

Dr. Philip E. Oyer, who headed the team performing Wednesday's six hour operation, told a news conference that the fist-sized implant was functioning "as good as, or better than, we could have hoped."

Surgeons and cardiologists had decided Tuesday that the experimental Pulsemaker Heart Assist System offered patient Robert St. Laurent, 51, Ft. Lauderdale, Fla., the best hope of survival until a heart transplant donor could be found, said Oyer, a Stanford associate professor of cardiovascular surgery and pioneer in the device's development.

The operation was the first implantation of a heart assist device performed at Stanford, although nationwide during the last few years more than 200 patients have been outfitted with various temporary devices that supplement the heart's pumping action.

However, Oyer told reporters that the device implanted Wednesday offered the best of hope of serving as the nucleus of a future, totally implantable portable system. He said it was the first left ventricular assist device (LVAD) based on an electronically driven—rather than pneumatically driven—pumping action to be implanted in a human patient.

The new LVAD will be refined during the next two to three years into a system which could potentially support a patient without requiring him to be connected to a large, nonportable console.

He added, however, that "transplantation rather than a mechanical assist device remains the first choice for those patients who qualify" because a natural heart which does not require an external power supply, offers better quality of life.

Oyer said the LVAD might prove useful for patients who were too old or otherwise medically unsuitable for a transplant, and as in the present case, as an interim device to be implanted until a suitable donor organ becomes available.

He said the LVAD and heart transplantation were complementary technologies.

Norman Shumway, cardiovascular surgery department chairman, added, "When there is a chance that a damaged heart can recover with time, a temporary assist device would be preferable to transplantation."

The present device, which takes over 80 percent of the heart's workload, will remain implanted in the patient temporarily, allowing his own heart to rest. If all goes well, the pump will be removed within two weeks as soon as the patient's heart is strong enough to take over temporarily until a donor is found, doctors said.

The average wait faced by transplant candidates is approximately six to eight weeks, Oyer said, but an intensive search is currently under way to find a suitable donor while the temporary implant is in place.

Oyer said St. Laurent was accepted for the transplant program on July 6. For at least four years, St. Laurent had been so ill from coronary atherosclerosis (hardening of the arteries), that he had been unable to work at his job as general manager of a recycling plant.

Oyer said St. Laurent had undergone previous double bypass surgery but that doctors had determined that without a transplant he had no more than a few months to live.

On Aug. 24, his condition had deteriorated and he was fitted with an intraaortic balloon pump, a balloon-like device inserted into a major artery which through expanding and decreasing air pressure can augment cardiac function about 10 percent, Oyer said. But chest pains continued and his condition deteriorated to the point where more aggressive temporary action was needed to keep the patient alive until a suitable donor could be found.

Cynthia St. Laurent, the patient's wife, said, "I am very grateful to Dr. Oyer and the other doctors for giving my husband a chance to buy some time until a suitable donor heart is available."

The new device, manufactured by Novacor Medical Research Corp. of Oakland, takes over for the left ventricle, the muscular workhorse heart chamber that pumps blood into the body's 60,000-mile network of blood vessels.

The Food and Drug Administration (FDA) in July granted approval for human testing of the LVAD, which has been under development for more than a decade by Stanford physicians and scientists at Novacor.

Oyer added that although development of the long term implant is still under way, more than 10 years of laboratory and animal testing paved the way for the FDA's recent approval of the temporary device for human trials.

Stanford and Novacor have permission to place the device in up to 20 patients.

Patients who take a sudden turn for the worse while waiting for a heart transplant, or those whose hearts unexpectedly fail during open-heart surgery but are thought to have a good chance of recovering if their own hearts are given several weeks of rest, are among the potential candidates for implantation, Oyer said. The device has not been approved for patients who are in the process of having a heart attack, he added.

The device is hooked to the failing heart and sits below it in the abdominal region. It draws blood from the patient's own weakened organ and pumps the blood around the body, taking most of the burden off the sick heart muscle and giving it a rest.

The implantation of this first generation mechanical device by Stanford cardiovascular surgeons known worldwide for their pioneering heart transplantation program, will not represent a shift in focus from transplantation, Oyer said.

The plastic pump encased in a metal housing was installed between tissue layers in the patient's abdominal wall. Blood is shunted to the pump through a dacron conduit from the left ventricle. The pump ejects blood back into the circulatory system through another dacron tube leading to the aorta.

The LVAD is linked by a cable passing through the patient's abdominal wall to a bedside control console that provides power. The console also holds computerized equipment that monitors the heart's beating pattern and directs the pump to beat in synchrony with the patient's natural cardiac rhythm.

The new pump has been under development since 1972 by Stanford and Novacor researchers. Peer Portner, chief executive officer of Novacor, has directed engineering research and development of the device in collaboration with Oyer who, over the years, has received options for Novacor stock. Portner is also consulting associate professor of cardiovascular surgery at Stanford.

The Novacor device incorporates several design improvements over previous LVADs, Oyer said. The most important of these is that unlike the prevalent pneumatic systems—whose mechanical action depends on bursts of compressed air fired through a tube that enters the patient's body—this pump is electronically controlled and activated.

In the future system currently under development and probably available in about three years, the power/monitor computer will be miniaturized to a size that can be completely implanted inside the body. A belt worn around the waist will be capable of transmitting power through the intact skin to the implanted components of the permanent LVAD.

The belt transformer will do away with the need for wires that pierce the skin, which are a potential source of infection, Oyer said.

Like an artificial heart, an LVAD is installed at the present time only in patients for whom more conventional therapy has been ineffective and who would die without the mechanical aid, Oyer explained. Current LVADs are primarily for patients who need to be tided over a critical period of heart failure, he added, and only for patients whose own diseased hearts are likely to recover during the few days or weeks the device remains in place.

In addition to potential heart transplant patients having difficulty surviving until a donor is found, such as the current patient, other candidates include patients having recent heart surgery who are in cardiogenic shock and whose own hearts cannot provide the blood pressure needed to maintain circulation, and open-heart surgery patients who cannot be weaned from the heart-lung bypass machine immediately following an operation.

Oyer estimated that Stanford may perform between five and 10 implantations in the next year. Clinical trials could expand to other medical centers within a year or two, he added, if the device proves effective.

In a study for Novacor, the consulting firm SRI International estimates that more than 100,000 patients today could potentially benefit from a permanently implantable version of the LVAD.

According to Oyer, survival rates were poor with LVADs tested in the 1970s; fewer than 25 percent of patients survived long enough to be weaned from the pump and discharged from the hospital. More recently, survival rates for patients with temporary LVADs have increased to nearly 50 percent, he noted.

Other centers that have tested LVADs include Pennsylvania State University in Hershey, Washington University in St. Louis, Boston Children's Hospital, the Cleveland Clinic, Presbyterian Medical Center in San Francisco, and the Texas Heart Institute, Oyer said.

The Stanford/Novacor device has been tested in approximately 150 calves and sheep, some of which lived with the device for as long as six months, Oyer reported. Further development and animal testing is necessary before the fully implantable LVAD can be considered in humans, Oyer said, to prove that the pump and its components can work continuously for a duration of several years. These studies on the long term LVAD will be carried out over the next three years, he said.

Although the patient will be tethered by cords to the external console with the present temporary device, the limited mobility is no different from being dependent on other types of life-sustaining devices for a few weeks, Oyer said.

The totally implantable LVAD, once it becomes available, will include a small rechargeable battery pack allowing the patient to become untethered. An implanted battery will be designed into the system to provide up to an hour or two of device operation free of any external electrical power.

-more-

"It is primarily because of this dependency on an external power source for all patients with mechanical cardiac support devices of any kind, that we believe cardiac transplantation, which allows complete freedom and mobility, will offer the better quality of life for the foreseeable future," Oyer said in an interview before the operation.

The pump itself is straightforward. Two pusher plates that form the device's opposite sides move together to squeeze blood out of the chamber. As blood refills the internal sac, the plates pivot apart.

The pump's rhythm is controlled by a microprocessor that tells it when to beat, and how forcefully. In most cases, it is programmed to beat in synchrony with the patient's own rhythm, Oyer said, although it also has the capacity to beat at a steady predetermined rate, irrespective of the patient's own heart rate. It can adjust automatically for increased exertion and can beat up to 180 times per minute, a pulse rate achieved during strenuous exercise by an active young adult, he added.

The surgical implantation procedure is relatively simple, Oyer said. The pump and supporting components are installed in the abdominal region below the heart.

While blood is detoured around the heart through a heart-lung bypass machine, incisions are made in the heart and the aorta, the major artery leading from it. Through a small puncture made at the bottom of the left ventricle, a tube is placed so that blood can flow into the pump. Another tube leads from the pump to the aorta, returning blood to the circulatory system. These tubes are plugged but left in place when the LVAD is removed.

Animal tests have revealed some medical complications that could develop with LVAD use, Oyer said. In short-term use, there is a small possibility that blood clots could form within the device and travel to other parts of the body, such as the brain, causing stroke. There is also a small risk that blood components could become damaged, causing bleeding problems, he added. And there is a slight chance of mechanical or electrical failure in the LVAD itself, he said.

Long term studies in animals point to added potential complications when the device is implanted for more than a few months, including a buildup of calcium deposits on the device's valves, and blockage of the dacron tubes due to layering and growth of cells on the inner surfaces. These complications may not occur in adult humans, Oyer said, but might be unique to the young, growing animals tested, whose metabolism is different from adults. Further testing in adult animals—particularly in sheep whose hearts are closer in size to humans—is ongoing, he added.

Some other drawbacks may crop up for patients on the LVAD, Oyer added. Some individuals could be disturbed by the pump's vibration and noise generated by the pump as it empties and fills, he said. But although mobility is limited by the external console in the current device, freedom of movement will become much greater when the belt model becomes available, he observed.

GLICK HONORED BY PROFESSIONAL GROUP

STANFORD—

Dr. David Glick, Stanford professor emeritus of pathology recalled to active duty in the department of radiology's Cancer Biology Research Laboratory, was unanimously elected an honorary associate of the Congresses of the International Federation of Societies for Histochemistry and Cytochemistry, at the group's meeting held last month in Helsinki, Finland.

Currently there are only two honorary associates, Glick being the second member named. The position is confined to persons eminent in the field of histochemistry and cytochemistry who have also given distinguished services to the Federation.

Glick also delivered the first lecture in his name at the meeting. The David Glick Lecture was established in 1983 by The American Histochemical Society. Glick's topic was, "Fifty Years with Histochemistry and Cytochemistry."

STANFORD HOSTS NIH/FDA CONFERENCE

STANFORD—

"The Protection of Human Subjects in Research: Ethical and Practical Issues" is the topic of a regional workshop sponsored by the National Institutes of Health (NIH) and the Food and Drug Administration (FDA), to be held at Stanford University Sept. 13 and 14.

Keynote speaker at the conference will be NIH's deputy director, Dr. Thomas Malone. Representatives of NIH and FDA will be present to discuss current aspects of federal regulations and to respond to questions.

General sessions will focus on the history and current status of NIH/FDA human research subjects regulations, implementation of the regulations in the research environment, and ethics: theory and practice.

Topics of individual workshops may include overseas research, privacy and confidentiality, deception and hypnosis as research tools, vulnerable subjects (children, mentally incompetent, prisoners, others), balancing risks and benefits, innovative treatment and research in the emergency room, ethical issues in drug research, the consent process, and others.

The conference is open to everyone with an interest in research, and should be of special interest to: members of institutional review boards; investigators whose research involves human subjects, whether biomedical, social or behavioral science; administrators and staff responsible for implementing federal regulations and institutional policy regarding the use of human subjects; researchers whose projects involve investigational drugs or devices; individuals interested in ethical issues in research; and research sponsors.

A registration fee will cover workshop sessions, dinner Sept. 13, and lunch Sept. 14. Enrollment is limited, so early registration is advised. A detailed program including workshop faculty, accommodation and other information is being mailed to registrants.

For further information and registration, call Phyllis Hall of the sponsored projects office at (415) 497-3638.

MEDICAL CENTER OPPOSES BALLOT PROPOSITION'S IMPACT ON BALLOT

STANFORD—

The public, especially children, will be the real losers if Proposition 41 passes next Tuesday, Nov. 6, said Stanford University's vice president for medical affairs, Dr. Lawrence Crowley.

The measure would limit California per capita expenditures for MediCal and Aid to Families with Dependent Children (AFDC) to 110 percent of the average per capita expenditure in the other 49 states.

In an Oct. 26 letter to the approximately 10,000 faculty and staff of the university and Stanford Hospital, Crowley said, "I hope you will consider the devastating impact on health care if this legislation passes.

"I, therefore, strongly urge you to vote NO on Proposition 41 and to share this information with your family, friends and colleagues."

The vice president, affirming that the university and hospital as institutions "have taken a position against this legislation," said the victims of the measure would "be aged, blind and disabled Californians and children, those least able to fend for themselves."

Children, said Ronald Hill, a Stanford University Hospital administrator, would be especially hard hit, since 30 percent of the newborn infants requiring intensive care and 21 percent of all newborn infants delivered at Stanford were provided care under the state MediCal program. Excluding newborns, 10 percent of the more than 20,000 patients discharged annually were subsidized by MediCal last year.

Crowley said that if Proposition 41 passes Nov. 6, the hospital and clinics "will be asked to absorb substantial additional reductions in reimbursement. We will then be forced to make difficult choices which may adversely affect our patients."

Also opposing the ballot measure was the hospital's medical board, representing all of the more than 1,000 faculty and community physicians who practice medicine at the hospital.

"Proposition 41 is not 'welfare reform' but an attack on those in our society who are most needy," read the resolution adopted unanimously by the board Oct. 25. In urging a no vote, the board said the measure "would cause great harm to some of our neediest and least protected citizens."

The board estimated that under the measure "more than 1,200,000 children may be deprived of basic health services."

In an interview, Crowley said it was impossible to predict precisely where statewide cutbacks in health care would have to be made, since the initiative does not earmark specific programs for cutbacks.

10-30-84

-more-

Currently Stanford has contracted with MediCal for payment on a flat-fee daily basis for patients. David Sakai, director of finance for Stanford Hospital, said the amount (which by law remains confidential) is so low that any cuts would mean that Stanford would have to reassess whether it could remain a MediCal provider without negatively impacting care to other patients.

But he added that the most debilitating cuts affecting patients could involve reimbursements for special services, including medications, eyeglasses, hearing aids or transportation from other facilities.

The state, said Sakai, has a number of ways to meet the spending limits which would be imposed by Proposition 41. Eligibility could be limited, lower rates could be paid to hospitals and other health care providers, services could be centralized at a few facilities, such as county hospitals, and/or the range and scope of services could be reduced.

"It is likely that the state would have to look at all or most of these alternatives if Proposition 41 passes," said Sakai.

Since the cost of living in California is significantly higher than in other states such as Arkansas or Mississippi, expenditures for affected welfare programs have been higher and would be cut from the current levels of about $6 billion to $3.1 billion. If cutbacks were made proportionate to present funding, AFDC would be cut 60 percent, while MediCal would be reduced 36 percent, according to the state legislative analyst.

Sakai said "the most insidious aspect of Proposition 41 is that it not only makes massive, debilitating cuts, but because reimbursement is tied to average expenditures in other states, it makes those cuts unpredictable, always based on costs of a previous year."

While the precise effects of the measure remain uncertain, Crowley and faculty physicians responsible for treating patients have said they are convinced that programs would be harmed if the measure passes.

For example, many of the more than 900 newborn babies treated each year in the neonatal intensive care unit are transferred shortly after birth from hospitals as far south as San Luis Obispo.

"If Proposition 41 passes, most likely medical transportation will be cut from MediCal reimbursments," said Dr. David Stevenson, assistant professor of pediatrics and associate director of newborn nurseries.

"Other hospitals just don't have the facilities or if they do, they don't take MediCal patients," he said.

Sakai and Stevenson both noted that the proposition threatened to create a vicious circle which would increase overall health costs for the needy by denying all but the most urgent care.

Stevenson said that women who could no longer receive prenatal care would stand an increased chance of having babies with developmental problems ultimately requiring more expensive care than if the problems had been prevented early.

"The proposition will backfire if its intent is to cut costs," said Stevenson. Since so-called optional services, including preventive care, would probably be the first to be cut, health care would be deferred until a more expensive emergency occurred.

Other Northern California hospitals have publicly opposed Proposition 41. Children's Hospital at Stanford, a separate but educationally affiliated facility with Stanford Hospital, has said that Proposition 41 would mean a cut of about $2.5 million in an overall budget of $21 million.

The University of California at San Francisco, which manages five medical centers, has said that "If passed, this measure could make ineligible many patients who now receive health care at the University of California, San Francisco."

MEDIA ADVISORY

Editors, Reporters:

Stanford University Hospital's department of dietetics is sponsoring its third annual conference on Recent Advances in Nutritional Care, starting 9 a.m. Thursday, Nov. 1, in the M building of the medical center.

Although the conference is intended for health professionals, some speakers will be available for interviews. Reporters are invited to attend sessions. They should check in at the registration desk.

After lunch the program will move to Fairchild Auditorium, located in the southwest corner of the medical center. Limited parking is available in employee parking lots.

Conference topics will include "Osteoporosis: Causes, Treatment, Prevention," with Dr. Robert Marcus, associate professor of medicine (clinical), and research dietitian Ann Coulston; "Progress and Possibilities in Achieving Regression of Atherosclerosis," with Dr. John Farquhar, professor of medicine; and "The Calcium and Blood Pressure Hypothesis: A New Direction for Hypertension Research," with Dr. Cynthia Morris, an epidemiologist from The Oregon Health Sciences University. Other Stanford and guest speakers will also be featured.

"The Prospects are Extraordinary," a multi-image slide show presentation on academic medicine at Stanford, will be shown.

For further information call (415) 497-6904.

VOLUNTEERS NEEDED FOR PANIC ATTACK STUDY

STANFORD—

Volunteers are needed for a study to determine the effects of different anti-anxiety medicines in patients with panic disorders or panic attacks—sudden periods of intense fear or discomfort usually reaching a peak within 10 minutes, and occurring in other than life-threatening circumstances.

Researchers in Stanford's department of psychiatry are interested in investigating the physiological (including cardiovascular) changes that may accompany some promising new pharmacological treatments for reducing the frequency and intensity of panic attacks, which can be precipitated spontaneously or by an external situation.

Participants will receive in-depth physical and psychological assessments at the beginning and end of treatment. There is no charge for the eight-week treatment program, which includes extensive monitoring.

To qualify for participation in the study, a person must experience a minimum of one panic attack per week, be willing to take oral medication, and be able to attend clinic appointments over approximately a 13-week period. Persons already on medication may still qualify.

For further information or to volunteer, call Dr. Mary Southam at (415) 497-5065.

SCIENTISTS REPORT FUNDAMENTAL DISCOVERY ABOUT IMMUNITY

STANFORD—

Scientists at Stanford University School of Medicine and Massachusetts Institute of Technology have announced the isolation from mouse cells of a new type of gene believed to regulate the recognition signals of the immune system.

At the same time, scientists at the National Jewish Hospital and Research Center in Denver, Colo., reported they had sequenced the chemical building blocks of the protein corresponding to this gene from human cells.

The work is considered important because defense cells depend on signals to tell friend from foe, including the self, invading viruses and bacteria, and organ transplants. Failure in this recognition can lead to infection, cancer and autoimmune diseases such as some allergies and rheumatoid arthritis in which the body perceives its own tissues as foreign and attacks them.

The newly discovered gene, made up of a small fraction of the hereditary material DNA, contains a blueprint of amino acids, chemical building blocks, for the alpha chain of the T-cell receptor.

Receptors are chemical configurations on cell surfaces which act as keys in a lock-and-key recognition system. The T cell receptor consists of two linked chains of amino acids. They are known as the alpha and beta chains and are considered important in understanding of the T cell. The chemistry and genetics of the beta chain in both mouse and human cells had been identified by the same Stanford group that did the recent work and Canadian researchers under Dr. Tak Mak at the University of Toronto earlier this year.

To work properly, the immune system depends on two major types of cells, called B cells and T cells. The identity of B cell receptors has been known to scientists for a long time, but the mysterious nature of the T cell only began to be unraveled about two years ago through use of sophisticated biochemical techniques.

If the surface of a parasite or virus, for instance, fits the receptor on the surface of the B cell, the cell simply produces antibodies against the invaders.

T cells, however, play a variety of roles in the immune system, including regulation of the actions of B cells. They also control the body's immune response to organ transplants, and can kill viruses directly and certain types of tumor cells.

The new discoveries were reported independently by the Stanford, MIT, and Denver groups in the Nov. 1 issue of the prestigious scientific journal *Nature*.

10-29-84

-more-

The Stanford effort was led by Dr. Mark Davis, assistant professor of medical microbiology. His collaborators were Dr. Yueh-hsiu Chien, a senior research associate; Daniel M. Becker, a medical student; Dr. Tullia Lindsten, a postdoctoral fellow; Maki Okamura, an undergraduate student; and Dr. David Cohen who is currently with the Laboratory of Immunology of the National Institute of Allergy and Infectious Diseases at the National Institutes of Health, Bethesda, Md.

The leaders in this research at MIT are Dr. Susumu Tonegawa and Dr. Haruo Saito. The MIT group last summer reported in *Nature* the isolation of a gene which appeared to be the alpha chain, but subsequent biochemistry indicated it is a third T cell receptor-like gene of unknown function.

The group at Denver's National Jewish Hospital and Research Center was headed by Dr. John Kappler and Dr. Phillipa Marrack.

"We now have defined the chemistry and genetics of the two complete chains that make up the T cell receptor," Davis said. "A problem, however, yet to be determined is what the third gene isolated by the MIT group does."

T cell receptors must recognize "foreign" invaders so that they can mount a defense against them, he said. They must also deal with the recognition of "self" so that they can be prevented from generating antibodies against their own tissues. This recognition is determined by molecules in a region of the body's defense system known as the major histocompatibility complex (MHC).

MHC molecules, Davis explained, are polymorphic. They are of different types scattered throughout the population. And because their function is to scan cell surfaces for abnormalities they create havoc among transplant patients whose new organs they view as abnormal.

"One needs both the beta and alpha chains to understand more fully the function of the T cell receptor," Davis said. "The more we know about T cell immunity and how cells recognize abnormalities, the more we will be able to do something about augmenting T cell responses to diseases. The major job of putting down cancerous cells, for example, seems to involve T cell defenses."

By the same reasoning one could reduce T cell responses in organ transplants such as kidney and hearts where rejection is a major problem and must be suppressed by powerful but dangerous drugs. New insights on T cells and their role in the regulation of the immune system could lead to new methods of dealing with transplant rejection.

In a commentary on the discoveries, *Nature*'s lifesciences editor Miranda Robertson said that "with all the relevant genes now isolated" it should be possible for scientists to design experiments that will answer many fundamental questions concerning the immune system's mechanism of dual recognition.

FOR IMMEDIATE RELEASE

BLACK ENROLLMENT FALLS AT STANFORD MEDICAL SCHOOL

STANFORD—

For the first time in 15 years, Stanford Medical School has failed to enroll as many black students in its fall entering class as it has in the past.

Of ten black students—nine males and one female— offered places in the school this year, eight chose to go elsewhere and two deferred their enrollment for a year, director of admissions Dr. Raymond Clayton said Tuesday, Oct. 23.

The number of minority students in the entering class of 86 this year is 11 or 13 percent, contrasting sharply with 18 students or 21 percent last year, Clayton said. Of the 11 minority students enrolled, three are native Americans and six are Chicano. Two admissions are blacks, but they are deferrals from last year.

The problem is a source of deep concern to the medical school's faculty senate, which Friday (Oct. 19) passed a unanimous resolution reaffirming its commitment to "identify, select, and matriculate highly qualified minority students."

The resolution, which must be approved by the faculty electorate, notes the senate's disappointment that only two black students have enrolled this year in contrast to Chicanos and native Americans, who are well represented.

"We reaffirm the commitment undertaken by several previous senates to maintain a vigorous affirmative action program," the senate said. "The social justification for such a program has not diminished.

"The senate does not consider a quantitative nor proportional quota of matriculated minority students desirable nor acceptable. The senate reaffirms, however, its goal for Stanford University School of Medicine to be a leader among comparable medical schools in matriculating highly qualified minority students."

Dr. Fernando Mendoza, assistant dean for student affairs, said multiple factors are undoubtedly behind the problem, and until they are analyzed and addressed, "we will continue to see a drop in minority student enrollment."

"We are puzzled by the result," Clayton said. "We are studying the characteristics of this year's applicant pool compared to the last to determine if they were different."

Stanford's higher tuition costs and tougher competition for minority applicants from other Ivy League medical schools and the University of California may have been in part responsible for the problem, he said.

10-23-84

-more-

Since 1969 when Stanford began its affirmative action program, there has been an increase of minorities in the student body averaging 20 percent in recent years. Minorities have included black, Chicano, mainland Puerto Rican and native American students, associate dean for student affairs John Steward explained.

"We we have been a leader in this field and consistently ahead of the national average which has been about 8 to 9 percent," he added. "We have matriculated 252 minority students and the attrition rate for academic reasons has been 10 students."

A 1981 report from the Office of Statewide Planning in Sacramento had singled out Stanford's medical school as "the model" of how to attract and enroll minority medical students. Stanford's minority enrollment of 26.7 percent that year was the top in the state, the report said. It urged the University of California system to step up its affirmative action programs to meet goals similar to Stanford's.

Since then, Steward said, UC and other medical schools have increased their minority recruitment, which in part may explain the lower number of students enrolling to Stanford.

Students offered places at Stanford a year ago, but instead chose UC medical schools, were surveyed by the admissions office. The students said they chose UC because it provided a comparable education and good clinical training at a fraction of the cost. (Stanford medical school's 1984 tuition is $3,808 per quarter compared to UC's $463 tuition and education fee charged to California residents and $1,651 to nonresidents.)

But costs may account only partly for the lower enrollment, said Dr. Roger Peeks, assistant dean for student affairs. Peeks, a Stanford alumnus in practice in Oakland, co-chairs with Mendoza the minority advisory panel which reviews applicants and makes recommendations to the admissions committee.

"It's true," he said, "students choose cheaper medical schools, but this doesn't explain the sudden drop in enrollment. The cost issue was with us last year, too, but we were successful in maintaining our affirmative action record. I don't think it's a valid argument.

"Stanford really has been the gold standard for minority recruitment," Peeks said. "There is no reason why it can't continue to be. One way to compete better with other schools is to address a widespread misperception about the school's clinical programs, which some say do not have the clinical emphasis that they should.

"Personally, having gone through training here, I believe Stanford is an excellent place clinically. But as long as this myth exists many students will go elsewhere. The school and faculty must take steps to set the record straight."

FAMILY OFFERS $5 MILLION FOR MENTAL ILLNESS RESEARCH

STANFORD—

The Pritzker family of Chicago has presented a $5 million challenge gift to the Stanford University School of Medicine to support resarch on the biochemistry of mental illness, the medical center announced Wednesday (Oct. 23).

The gift is the first given to Stanford to endow a research laboratory, said Dr. Jack Barchas, professor of psychiatry and behavioral sciences.

The funds will support the research program of the Nancy Pritzker Laboratory of Behavioral Neurochemistry, headed by Barchas. The gift will also seed a Medical School drive to raise an added $15 million to support other programs and capital projects in the psychiatry department.

Funds raised from the $15 million drive may support professorships for faculty and fellowships for predoctoral and postdoctoral trainees, new quarters for the department, and expansion of the department's mental health clinical research centers for children and adults. Barchas said funds might also be used to support various other programs, such as Stanford psychiatry laboratories dealing with developmental neurochemistry and sleep disorders.

In addition, funds will be applied toward construction of a planned magnetic resonance center, which Barchas described as a promising new tool for psychiatry research, and toward acquisition of an inpatient psychiatric facility.

"Our gift should enable Stanford to encourage other donors to participate in improving the financial stability necessary for effective teaching and research in the department of psychiatry at Stanford, already known worldwide for its excellence," said Jay Pritzker, who announced the gift recently for his family.

"This splendid endowment helps a crucial area of mental health research, and gives other donors a powerful incentive to support a psychiatry department that is outstanding in its commitment to studies of biological and psychosocial factors in severe mental illness of adults and children," said Stanford President Donald Kennedy in acknowledging the gift.

The Pritzker laboratory focuses on the biochemical basis for mental health and disease. Its work centers on molecular messengers in the brain called neurotransmitters.

In recent years, researchers in Barchas' lab have studied how abnormalities in control of these chemical links between nerve cells may be important in forms of severe mental illnesses, such as depression, schizophrenia, and some addictive states, Barchas said.

"There has been an explosion of knowledge that needs to be explored," said Barchas, "yet researchers in the field of psychiatry have less money available in real dollars today than in 1969."

Half the beds in U.S. hospitals are devoted to patients with some form of psychiatric illness at a cost of more than $185 billion per year in lost productivity and medical expenses, Barchas said. However, the researcher said that annual spending for mental illness research is only $5 per patient, compared with about $20 and $160 per patient, respectively, for heart disease and cancer.

The Pritzker family and the Pritzker Foundation have supported mental health research at Stanford Medical School since 1976, when the Nancy Pritzker laboratory and Nancy Friend Pritzker Professorship were established in memory of Stanford student Nancy Friend Pritzker, daughter of Mr. and Mrs. Jay Pritzker.

PHYSICAL THERAPY STARTS SCHOOL FOR BACK SUFFERERS

STANFORD—

Physical therapists at Stanford are hopeful that patients may learn to help control their own low back pain by attending a school equipped with mops, brooms, garden tools and a kitchen.

The Stanford Back School, sponsored by the Department of Physical and Occupational Therapy, begins classes this month.

"Unlike more passive traditional treatment, the school helps patients take charge of their own health care through an understanding of their condition and through implementation of very practical physical, nutritional and even psychological tools designed to alleviate suffering, said Terry Nordstrom, the physical therapist who directs the school.

Nordstrom said the curriculum is an based on programs started in Sweden in 1970 and adapted to current medical knowledge and technology.

"This school is consistent with the idea that American patients in the mid-1980s want to understand and manage their own health care as much as possible. Back pain control is extremely conducive for this sort of intervention," said Nordstrom, "because many of the things which will help people alleviate their pain are things which they need to learn to do in their everyday lives. Once they learn a few relatively simple techniques, many sufferers will be able to lead more active lives."

The everyday objects, including mops and brooms and a model flower bed, will enable patients to practice using the proper techniques to accomplish everyday tasks with a minimum of discomfort and potential for injury, Nordstrom said.

Patients will first be put through an obstacle course, consisting of typical work tasks. Physical therapists will monitor and photograph the lifting, sitting, or stretching movements to suggest ways of improvement, Nordstrom said. Exercises and resting postures intended to relieve pain will be demonstrated and practiced, and lectures on basic anatomy will be given, Nordstrom said.

Classes consist of four once-weekly evening sessions, he said. Instructors include physical therapists, occupational therapists and registered dieticians.

Nordstrom said the program is geared toward a variety of chronic, mechanical back problems. Persons suffering from back pain caused by an underlying illness probably will not be eligible, and patients should wait for severe acute pain to lessen before starting the program.

Patients must be referred by a physician, undergo a physical exam and complete a written questionnaire before admission. Cost of the program is $20 per session, plus the cost of the initial screening.

FOR IMMEDIATE RELEASE

RESEARCHERS DESCRIBE UNUSUAL HEART PAUSES

STANFORD—

A small number of people whose hearts periodically stop for more than two or three seconds during sleep, and who complain of symptoms such as lightheadedness or fainting, may be helped by artificial pacemakers, reported Stanford scientists Thursday (Oct. 18) in *The New England Journal of Medicine*.

Their findings are based on case reports of four young, otherwise healthy adults, whose 24-hour electrocardiogram (ECG) recordings nevertheless disclosed up to 20 lapses in heart beat (asystole) of up to nine seconds each during rapid eye movement (REM) sleep.

"Although we're describing what probably amounts to a very unusual occurrence, we do know that a small number of patients die suddenly from bradycardia (slowed heart rate), or asystole—though usually there's an underlying disease," said Dr. Anne Gillis, a research fellow in cardiology and co-author of the study.

"During sleep, the heart rate normally slows in everyone," said Gillis. The researchers speculate that in their patients, there is an imbalance causing a greater-than-usual dominance during sleep of the parasympathetic tone, the component of the autonomic nervous system which is responsible for that slowdown.

Two drugs tested on the patients, atropine sulfate and protriptyline, found effective but discontinued because of adverse side effects, both work by inhibiting the action of the parasympathetic tone, Gillis said.

Three of the four patients had experienced symptoms believed to be related to the underlying rhythm disturbance, she said. These included feelings of faintness or actual loss of consciousness. But results of extensive evaluations, polygraphic sleep recordings, and electrophysiologic studies were normal, outruling sleep apnea or other disorders.

"REM sleep-related sinus arrests (as the heart pauses are referred to) . . . which may occur in apparently healthy subjects but are undetected, may explain some cases of sudden, unexpected death during sleep," the researchers headed by Dr. Christian Guilleminault, associate director of the Stanford Sleep Disorders Center, suggested.

What was found distinctly abnormal in their patients, Gillis explained, was the absence of heart beat for more than two or three seconds—the maximum duration considered normal.

"If a short lapse occurs it is because the heart's normal pacemaker, the sinus node, fails and the heart stops beating for a moment. But usually, other subsidiary tissues in the heart serve as back-up pacemakers (or escape rhythms) and start the muscles contracting again," Gillis said.

The three symptomatic patients were given artificial pacemakers to provide those back-up services usually occuring naturally in the heart, and two "have been asymptomatic for four and seven years, respectively, with this therapy, although 24-hour electrocardiographic monitoring continues to reveal the underlying problem," the researchers wrote.

10-18-84

-more-

If patients are asymptomatic to begin with, she said, no therapeutic intervention is needed.

Guilleminault and Gillis' co-authors are Dr. Peter Pool of the North County Cardiology Research Laboratory in Encinitas, Calif., and Dr. Jorge Motta, a former Stanford research fellow in cardiology who is now practicing in Panama City. Their work was supported by a grant from the American Heart Association, California chapter.

The patients sometimes experienced sinus arrest during waking hours as well, while engaged in bodily functions such as urination, defacation, sexual intercourse, or exercise, that are also characterized by a dominance of the parasympathetic tone, Gillis said.

While the phenomenon of sinus arrest occurring during sleep has been observed before, she said, this is the first study to specifically delineate the stage of sleep in which it was observed to occur.

But therapy should probably be the same regardless of whether sinus arrest occurs during wake or sleep, Gillis said, stressing that therapy is only needed when symptoms are present.

Although the patients experienced vague symptoms, the researchers said, it is possible their conditions would have remained unexplored and undetected had they not been medical personnel themselves and recruited for the studies.

The possibility of nighttime lapses in heart beat should be considered and evaluated in patients such as those described, the researchers urged. They suggest at least 24-hour ECG monitoring and, "for a more thorough evaluation, polygraphic monitoring during sleep."

ECG evaluation "might also be considered for patients with vague symptoms," if a routine study reveals no abnormalities.

Gillis said it was not known whether the brief heart stoppages could insidiously injure a patient's functioning, and this question should be further studied, the researchers concluded.

In an editorial appearing in the same issue of *The NEJM*, Dr. Leonard Cobb of Harborview Medical Center in Seattle said that asynchronous or quivering contractions known as ventricular fibrillation, usually caused by a structural degeneration of the heart muscle, is more often the mechanism involved in the hundreds of cases of unexpected cardiac arrest occurring each day in the United States.

Gillis, agreeing, added that ventricular fibrillation occurs mostly in patients with underlying vascular disease, such as blockage of the cardiac arteries.

"At present," Cobb wrote, "the four cases reported by Guilleminault et al. appear to be medical curiosities, and it seems unlikely that these observations have immediate relevance to the huge number of persons at risk of sudden cardiac death. Nevertheless, as Guilleminault et al. suggest, prolonged sinus pauses could conceivably be implicated in some instances of nocturnal cardiac arrest. Even so, it appears to be premature to propose that pacemakers be implanted solely on the basis of asymptomatic nocturnal bradycardia."

Guilleminault and Gillis plan to extend their research to the question of why some individuals appear to experience extra heart beats during sleep, and why the rare cases such as those described experience fewer.

FOR IMMEDIATE RELEASE

WAR ON PARASITES REVIVED BY $20 MILLION NATIONAL GRANT

STANFORD—

For pharmacologist Tag E. Mansour, a $20 million, five year study starting Dec. 1 means the resumption of a war on parasitic disease—which afflicts an estimated 1.5 billion people worldwide—after two decades of international neglect.

Mansour, who had his first grim look at parasitic diseases during his boyhood more than 50 years ago in Egypt, said Tuesday (Oct. 16) that he and six Stanford colleagues will join researchers from 11 other institutions in the study financed by the John D. and Catherine T. MacArthur Foundation, a Chicago-based philanthropic group.

"In a way, this consortium is a renaissance of the study of parasites which had almost died off when the developed nations withdrew from their colonies in the tropics during the 1960s," said Mansour, chairman of the Department of Pharmacology at Stanford.

"Most of the developing countries just stopped supporting research in this vital area when their own people were no longer affected. It has taken the initiative of a foundation to revive interest in finding treatment, cures, or prevention for one of the world's most serious health problems," the scientist said.

Mansour added that lack of support by developed countries may have been shortsighted even in their own interests, since international travelers are consistently exposed to parasites, offering the possibility of spreading the often-debilitating conditions here. Each year more than 300 U.S. travelers contract a single parasitic infection, malaria.

Each of the 12 participating centers in the United States, Australia, Israel and Mexico will study a particular aspect of parasitology, which includes such maladies as malaria, tapeworm, dysentery and schistosomiasis, African sleeping sickness. The MacArthur Foundation has estimated that more than half of the world's population is afflicted with at least one parasite.

Stanford received $1.5 million to apply the techniques of molecular biology and biochemistry to the study of parasite development and survival, potency and reproduction.

Other Stanford researchers include Paul F. Basch, professor of family, community and preventive medicine; John C. Boothroyd, assistant professor of medical microbiology; Ronald Davis, professor of biochemistry; Gordon Ringold, associate professor of pharmacology; Jack Remington, professor of medicine (infectious diseases); and Robert Schimke, professor of biological sciences.

Parasites are defined as small organisms that inhabit—and thus feed from—another organism, Mansour explained. They are similar to their smaller and less complex cousins, viruses and bacteria, but they have proven more difficult throughout the ages to control as a health threat to man.

"Because they are complex, it is harder to find a substance that will poison the parasite without harming the human or animal host they have invaded," Mansour said. Because of their ability to adapt, they often elude the body's own immune system, Mansour added.

2-2-2

What Mansour and his colleagues hope to do at Stanford is to understand the biochemistry, genetics and molecular structure of several of these organisms in hopes of finding ways of killing them without harming the human host. Another possible solution is to break the chain of the parasite's lifecycle, thus preventing their reproduction.

"What we basically are doing," said Mansour, "is searching for differences. If we can find a way of causing harm to a particular parasite without causing any ill effects to humans, we have achieved our goal."

Among specific organisms to be studied are toxoplasmosis, spread by unwashed vegetables, soil and cat feces. Unlike most parasites which are found in tropical or other underdeveloped nations, toxoplasmosis is present in about 50 percent of the U.S. population.

It usually remains dormant, says Remington who has specialized in this parasite for many years, but can become dangerous for unborn babies when their mother's contract it, or for acquired immune deficiency syndrome sufferers who do not have natural immunity.

Boothroyd plans to study the unusual way in which trypanosomes (cause of sleeping sickness in Africa) change their body surface to evade the immune system of the host.

Mansour is studying the metabolism of schistosomes, found in stagnant water throughout the tropics, which causes irreversible damage to the liver and kidneys. Mansour said about 200 million persons worldwide suffer from schistosomiasis. Currently the only treatment is long-term drug therapy with powerful agents which produce toxic side effects.

Basch will study the reproductive hormones in schistosomes with the hope of interfering with their egg production in the host.

Davis will produce new techniques for the isolation of genes from these parasites. Ringold and Mansour will use these techniques to study the genes of schistosomes so that they can isolate critical proteins that are used by the parasite to defend itself against the human immune system.

Schimke will study the mechanism of gene amplification, the parasite's ability to protect itself against medication,.

Mansour said research on individual parasites should produce useful information about other parasites.

He said prevention or at least cures for parasites are crucial to development of the third world. Some of the funding during recent lean years for parasitology has come from the World Bank "which has recognized that overcoming parasites is crucial to development in the third world. Development and productivity is impossible when a majority of the population in a country is too sick to work," Mansour said.

Although research efforts have declined in recent decades, Mansour noted that parasitology once had a high priority and early gains were important. In 1902, the second Nobel Prize ever given went to Ronald Ross, for his work in discovering the parasitic source of malaria.

Other centers in the MacArthur-backed consortium are Case-Western Reserve University, Cleveland; Columbia University, New York; Walter and Eliza Hall Institute of Medical Research, Australia; Harvard University and Massachusetts General Hospital, Cambridge, Mass.; Johns Hopkins University, Baltimore; National Polytechnical Institute, Mexico City; New York University Medical Center, New York; the University of California-Berkeley; The Weizmann Institute of Science, Israel; and Yale University, New Haven, Conn.

Jonas Salk, polio vaccine pioneer, is chairman of the health committee of the MacArthur Foundation's board of directors. The MacArthur Foundation was established by John D. MacArthur, sole owner of the nation's largest privately-held insurance company, and his wife Catherine. When MacArthur died in 1978, the foundation was endowed with the bulk of MacArthur's fortune.

BERG TO HEAD NEW MOLECULAR AND GENETIC MEDICINE CENTER

STANFORD—

Nobel Prize winning biochemist Paul Berg has been appointed director of Stanford University School of Medicine's proposed Center for Molecular and Genetic Medicine (CMGM).

Vice President for Medical Affairs Lawrence G. Crowley said Berg will oversee the futher development of CMGM's academic program, and the design and fund raising efforts for the building that will house the faculty research.

The field of molecular and genetic medicine promises dramatic changes for medicine in the future, Crowley predicted.

He said he and Stanford University President Donald Kennedy believe that "a strong program with emphasis on the continued discovery of new biomedical knowledge and its transfer into clinical applications and the amelioration of human misery is critically important for the future of Stanford Medical School."

Stanford trustees authorized planning for construction of the CMGM building in December 1983. Former Dean Dominick Purpura, who has since left for Albert Einstein College of Medicine, directed the initial planning with the assistance of a faculty committee.

The proposed Center for Molecular and Genetic Medicine will be a $45-million multistory building southwest of the Medical Center, with 90,000 square feet of laboratory and support space. Approximately 20,000 square feet will be leased to the Howard Hughes Medical Institute. It will house the laboratories of up to eight faculty members in the unit of molecular and genetic medicine whose research will be supported by the institute under an affiliation agreement with the Medical School.

The building will also house approximately 32 faculty members including a proposed new department of molecular and developmental biology, a department of molecular and cell physiology, and the department of biochemistry now located in the main center. The structure will also house a program in cancer biology and a small instrumentation development group, Crowley said.

The tentative schedule for the project calls for beginning of construction in 1985 and completion by the fall of 1987. The department of psychiatry building and other temporary structures now on the site will be relocated.

As CMGM director, Berg will report to the dean of the Medical School. Berg's chief objectives will be to develop and maintain a unified program involving several scientific disciplines, Crowley said.

He will be assisted by an executive committee composed of three faculty members who are eminent in their fields, Crowley said. They are Ronald Levy, oncology; Hugh McDevitt, medical microbiology; and Irving Weissman, pathology. Committee members will serve for specific terms. Newly appointed Medical School Dean David Korn will be an ex-officio member, Crowley said.

The center will include faculty who combine skills in clinical medicine with strong basic science training and research experience.

The 58-year-old Berg received the 1980 Nobel Prize in chemistry for his "fundamental studies of the biochemistry of nucleic acids, with particular regard to recombinant DNA." Berg was also responsible for shaping a policy for dealing with the possible risks of recombinant DNA research.

He has been on the Stanford faculty since 1950. Berg is a holder of the Jack, Lulu and Sam Willson endowed professorship in biochemistry. —30—

ACADEMIC MEDICAL CENTERS MUST FACE THE CHALLENGE OF A "CHANGING FRONTIER" OF MEDICINE, EXPERTS SAY

STANFORD—

Stanford University Medical Center may call upon its record of excellence created during its first 25 years, but it must tailor its emphasis to meet upcoming challenges in the field of medicine in order to survive the next 25 years, agreed speakers at Stanford University Medical Center Oct. 12.

The challenge facing academic medical centers, said Dr. Victor Fuchs, noted health care economist and professor of economics at Stanford, is to develop an understanding of and way to evaluate the consequences of medical intervention.

The "frontier" of medicine is changing, he said. Whereas at one time it was sufficient to discover that treatment "B" was better than treatment "A", now it's necessary to know how much better in order to determine its usefulness.

Fuchs was just one of the speakers at the medical center's 25th Anniversary celebration symposium—the first of a year-long series of events marking the move of the the medical center from San Francisco to the Stanford Campus.

The challenge medical centers face entails a change in the approach to medical education, Fuchs said. "For the established members of the faculty there is an understandable temptation to say 'we went to medical school. We went through housestaff training. We were successful. We know what is needed. Be like us. Do like us.' But in a dynamic environment that is a prescription for disaster."

"We continue to use primarily fact-filled lectures, examinations that measure recall almost exclusively, and oral confrontations on clinical rounds which see to reward the student who can either memorize the most facts or recall the most esoteric one. Factual knowledge is not enough," said Dr. Lawrence Crowley, vice president for medical affairs and president of Stanford University Hospital. "We must return the emphasis to teaching our students the basic concepts of normal and abnormal human biology, how to identify a problem and organize a logical approach to its solution and how to synthesize relevant facts and basic concepts with experience that will lead them to wise courses of action."

-more-

This change in educational methods and understanding of the effects of medicine is essential, Fuchs said, in light of the "economic squeeze" from the federal government and from the private sector on health care. While the economy as a whole has grown very slowly since the early 1970's, health care expenditures have kept going at a "boom rate", he explained. This has created an ever-increasing gap between the growth rates of the gross national product and health care expenditures.

Contributing to health care expenditures, he continued, is a tendency for individuals to use more health care services because, due to third party payment, they are not directly paying for them. Thus, they fail to measure the true benefits of those services.

"The health care system is like an 80,000-ton ocean liner going full speed ahead. It can't be turned around on a dime, but sooner or later it must reflect the underlying economic reality," Fuchs said.

"As a great center of research and education, Stanford must provide the analyses and understanding that will enable not only this hospital and this faculty practice plan, but health professionals and health institutions throughout the country to live with economic constraints while maximizing the health of the patients they serve," he added.

The tool to help achieve this, Crowley said, is the microcomputer. "It carries the potential of releasing the human brain from many of its more routine, time-consuming tasks, allowing more time for concentration on problem-solving and creative thinking."

Using computers, Fuchs added, will allow physicians to develop a quantitative picture of what happens to patients as they move through the health care system. With computers physicians can study the history of treated disease, "and evaluate quality of care as reflected in patient outcomes rather than simply inferring it from process or by the amount of money spent."

Medicine's future will be greatly influenced by the expanding knowledge of genetic engineering, Crowley said. With the knowledge of "perhaps being able to alter human evolution itself comes an awesome responsibility. The ultimate value of this new knowledge will lie in its application. We must not only educate our students and postdoctoral trainees thoroughly, but the public as well."

"We have at hand a chance to extend and deepen the results of the revolution in biomedical research," said Dr. Donald Kennedy, president of Stanford University. "At the same time we have the opportunity to lead a second biomedical revolution—one that will take the fruits of the first from the laboratory to the bedside." To do so successfully, Fuchs added, "will take the same qualities that were acted upon 25 years ago: vision, courage, a willingness to work together, and an eagerness to change."

FORMER CONGRESSMAN CALLS FOR "CITIZEN'S COMMISSION"

TO PROTECT ACADEMIC HEALTH CENTERS

STANFORD—

A federally-appointed "citizen's commission" should be created to ensure the continued viability of the nation's academic health centers, said former Congressman Paul Rogers Friday (Oct. 12).

Rogers spoke at Stanford University Medical Center's 25th Anniversary celebration symposium, the first of a year-long series of events marking the move of the medical school from San Francisco to the Stanford campus and the establishment of the medical center.

Rogers, D.—Fla., chaired the sub-committee on health and the environment in the House of Representatives until 1978, when he returned to private law practice in Washington, D.C.

"It will be necessary to make clear to the American people and to the Congress that academic health centers are truly a national resource," Rogers said. "Without the constant exploring in biomedical research, the excellence of clinical training and the delivery of quality health care, this nation's health care will deteriorate rather than advance."

Either the president or Congress should appoint the commission, Rcgers elaborated, which should include physicians, health professionals, educational leaders, and labor and industry leaders from throughout the country. Federal efforts to control health care costs by reducing government support of biomedical and behavioral research and medical education, and cutting back on reimbursement to hospitals are threatening the "vitality" of academic medical centers, Rogers said. "A record of extraordinary achievement is balanced against a future of unprecented uncertainty."

Because of the continuing interaction of basic scientist with clinicians, and of both with scholars from the humanities, academic medical centers are fertile ground for scientific discovery, the transfer of those discoveries into practical applications, and a forum to discuss and resolve social, ethical and public policy issues that accompany those discoveries, Rogers said.

10-15-84

-more-

Academic medical centers have also provided the nation with an ample supply of well trained physicians and other health care personnel, Rogers added. In 1959, the year the medical school relocated to the Stanford campus, the nation faced a serious shortage of physicians, he said. Today, he continued, people living in major cities and rural areas alike are served by specialists and primary care physicians, and a national network of tertiary care hospitals makes even the most acute care readily available.

In addition, academic medical centers serve as "critical way stations in the diffusion of new medical technologies from the clinical research laboratory to the community," Rogers said. "They serve to define and maintain standards of care through informal contacts with community physicians and through formal continuing education programs."

To ensure the continued productivity of academic medical centers, Rogers said, there must be a mutual understanding of what society expects from academic medicine and what medical schools need from society such as the following:

- The public wants medical schools to continue to develop better means of treatment. To do so, biomedical research must receive funding.
- The public wants to stop the rapid escalation of health care costs. Reimbursement methods must be reformed, and medical schools must place new importance on research designed to help control costs by training physicians to more selectively use costly modalities.
- The public wants a continued supply of well-trained physicians. Teaching hospitals must be fully reimbursed for their unique costs incurred because of their teaching function in order to allow them to compete with other physicians.

Academic medical centers are "organic units of teaching, patient care and research that cannot be dynamic if one of their limbs are wounded," Rogers said. "If our nation expects continued biomedical innovation, if we look to academic physicians to develop efficient modes of care, if we demand that new physician be well trained, and that established physicians be kept up-to-date, then academic medical centers and teaching hospitals must remain financially healthy and intellectually vital."

POSTMASTECTOMY GROUP THERAPY OFFERED

STANFORD—

Group therapy for women who have had a mastectomy and wish to deal with problems of self-image and sexuality will be offered by the department of psychiatry and behavioral sciences at Stanford University Medical Center.

To begin in late October and run for six months, the group will meet weekly for 90 minutes Mondays from 12 to 1:30 p.m. in the psychiatry building. It will be limited to 12 women.

"Women often regard themselves as they think the male sees them after a mastectomy (namely, as damaged goods), and they show this feeling by giving nonverbal signals which adversely affect intimate relationships," said Dr. Regina Kriss, a clinical instructor who will co-lead the sessions with Sandy Bacon, social worker.

The program is intended to provide new insights and opportunities for making better adjustments in self growth, marriage, and sexual relationships, Kriss said.

There is a fee which may be covered partially by medical insurance. For further information or registration, call Kriss at (415) 857-0857.

STANFORD CENTER FOR RESEARCH IN DISEASE PREVENTION FORMED

STANFORD—

The Stanford Center for Research in Disease Prevention has been formed to reflect the expanded activities of the Stanford Heart Disease Prevention Program (SHDPP), announced Dr. John W. Farquhar.

Farquhar, who has directed the SHDPP since its inception 13 years ago, said the move was prompted by an evolution of the group's activities, including an increasing public recognition and new scientific evidence that many of the risk factors for heart disease affect other conditions as well.

"While the majority of our research still concerns cardiovascular disease primarily, much of what we do is applicable to cancer, alcoholism and accidents," Farquhar said in a Sept. 17 memo to colleagues. The SHDPP will retain its name and activities as a component of the new expanded center, he said.

The group comprises of more than 20 faculty and staff from the fields of medicine, statistics, basic science, social science and communication research. Nearly 200 staff, including field personnel in several California cities, are employed on a full or part-time basis.

The diverse research activities have attracted more than $42 million in government and private grants since the program began in 1971 with the classic Three Community Study of health education.

Farquhar, a professor of medicine and family, community and preventive medicine, said he is confident that the broader, more complete name will encourage funding from agencies and potential donors outside the cardiovascular area.

One of the most recently funded programs, sponsored by a nearly $2 million grant from the National Cancer Institute, will study various long-term, self-help smoking cessation and maintenance methods, including nicotine gum and psychological aids.

The study, headed by Dr. Stephen P. Fortmann, assistant professor of medicine, will explore the premise that many people who wish to quit smoking prefer self-administered approaches. These programs need more study and evaluation, Farquhar said.

Other projects centering on non-cardiac health issues include an effort studying the relationship between the way the body burns food and calorie reduction. Principal investigators include Peter D. Wood, a professor of medicine; and William L. Haskell, clinical associate professor of medicine.

10-12-84

-more-

Fortmann, Wood and Haskell are associate directors of the center. The fourth associate director is Nathan Maccoby, professor of communication (emeritus).

The largest project currently underway is the Five City Project, a nine-year $24 million research effort involving 350,000 persons in five California cities. The program, an outgrowth of the original Three Community Study, is testing the idea that community health education programs can produce valuable decreases in heart disease.

The effort includes development and testing of such diverse educational methods as courses for health professionals, television public service announcements, brochures, and organized quit smoking contests.

Another current project is intended to develop a health education curriculum that teaches adolescents the skills needed to take charge of their health. Collaborative studies with the division of cardiology are examining ways to prevent atherosclerosis (hardening and clogging of the arteries), as well as cardiac rehabilitation.

The center's Lipid Research Clinic earlier this year reported results of a multicenter study in the United States and Canada which showed that reducing blood cholesterol levels can produce a distinct reduction in heart attacks.

Current funding for the fiscal year ending June 30, 1985 is $4.9 million, said Lillian O'Toole, administrator of the Stanford Center for Research in Disease Prevention.

Farquhar noted that in addition to ongoing research projects, faculty members under the center's auspices teach a cardiovascular disease prevention course for undergraduates in human biology and assist in the teaching of a human nutrition course in the medical school.

Farquhar teaches a medical school course in personal health; June Flora, education director of the Five City Project, teaches a "health communication" course for graduate students in communications; and Dr. C. Barr Taylor, a center associate and associate professor of psychiatry, teaches an undergraduate course on behavioral medicine.

The Health Improvement Program, created three years ago for the faculty, staff and families of the Stanford community, is a service, teaching and research component of the center.

The center is part of the university's Health Research and Policy Consortium.

TOXOPLASMOSIS WIDESPREAD BUT TREATABLE IN AIDS PATIENTS

STANFORD—

At least one common and potentially lethal disease afflicting patients with Acquired Immune Deficiency Syndrome (AIDS) is controllable with medication while researchers hunt down clues to the underlying ailment, a neurosurgeon said Friday.

Dr. Frances Conley, associate professor of neurosurgery at Stanford University, said that central nervous system toxoplasmosis is reaching epidemic proportions among AIDS patients. She presented the first of this fall's SMASH lectures Oct. 5. for the public.

"This disease, which used to be very rare, is now being diagnosed in my lab about twice a week, and the vast majority of cases are AIDS patients," she said.

"But if it's caught, it is very treatable with certain antibacterial drugs. If the index of suspicion of toxoplasmosis is as high as it now should be in doctors' minds, many AIDS patients suffering from it will be successfully treated while researchers continue to look for ways to reverse the basic immunity defect," she said.

"In the years between 1975 and 1981," Conley said, "Dr. Remington's lab knew of only six cases of central nervous system toxoplasmosis. From 1981 until the present, our two labs have diagnosed more than 100 cases of the disease." (Dr. Jack Remington, a professor of infectious diseases at Stanford and director of the department of immunology and infectious diseases at the Palo Alto Medical Foundation, is a world-recognized authority on toxoplasmosis. He spearheaded most of the work Conley described, she said.)

The double-sandwich staining technique Conley uses in her lab to diagnose the disease, using layers of antibodies and antigens aimed at delineating the infectious form of toxoplasmosis, was adapted for this particular use and has "really revolutionized our ability to look at what's happening in the brain," she said.

"It's an example of how a very basic science research project--which no one at first thought would have much future application—can, with a little serendipity, turn out to have tremendous clinical importance," she noted.

The technique was first used by Conley to examine the brains of immunologically healthy mice after they were injected with infectious toxoplasmosis. "We were working on the question of whether a chronic infection with toxoplasmosis would allow the brain to resist cancer, as it had been shown to do for the rest of the body," she said, "and we found that infectious toxoplasmosis actually prevents the development of brain tumors in mice with healthy immune systems," she said.

"Ultimately, we hope our studies will provide part of the background for the development of new therapeutic methods for people who have cancer or are at high risk," she noted.

Central nervous system toxoplasmosis, which causes quite varied symptoms including such problems as chronic headaches, confusion, lethargy, fever, and sometimes seizures and paralysis, will progress to coma and death if left unrecognized and untreated, said Conley, who is also chief of neurosurgery at the Palo Alto Veterans Administration Medical Center.

The tricky part about pinpointing the disease in people with AIDS, Conley said, is that this group's blood test results show up differently from those of non-AIDS patients who are infected. This is one reason physicians have often overlooked the possibility of the parasitic infection in their AIDS patients suffering symptoms of encephalitis. Since lab tests won't disclose the condition, Conley said, samples of actual brain tissue must be examined.

Conley and Remington published their observations in the Aug. 17 issue of the *Journal of the American Medical Association*. They suggest that physicians treating AIDS patients who are showing signs of central nervous system problems order CT scans to check for abnormalities, take biopsies on affected tissue, and run blood tests anticipating the type of skewed results they describe.

The drugs available for use upon diagnosis cause a wide range of side effects and must be used on a long-term basis. But they are effective, Conley said. Meanwhile, Remington and other researchers are testing alternative antibiotic medications every day. (Cortisone, often used for encephalitis treatment, is not effective and is even harmful when the condition is caused by toxoplasmosis, Conley said.)

A ubiquitous parasite that lingers harmlessly in about 50 percent of the U.S. population, Toxoplasma gondii can trigger deadly disease in people who are immunosuppressed, Conley explained. These may include cancer patients, organ transplant recipients taking immunosuppressive drugs, and AIDS patients, in whom the basic defect lies with the body's immune system.

The healthy immune system keeps toxoplasmosis dormant and under control in most healthy persons. It is spread through undercooked meats, unwashed vegetables, soil and cat feces. Symptoms are usually totally absent or are similar to a mild case of flu, Conley said.

But if the immune system is later impaired, the heretofore latent disease can become highly infectious. The ailment also becomes dangerous when a woman becomes infected during the first trimester of pregnancy, risking transmission of the disease—and the likelihood of major birth defects or stillbirth.

"We don't know exactly why," Conley said, "but the brain, the heart, and the retina seem to be the three most susceptible target organs for toxoplasmosis." This may be because none of them have large colonies of immunologic cells. "In fact, the brain is very tolerant to foreign substances," she said.

Groups at high risk for AIDS include homosexuals, Haitians, intravenous drug abusers, hemophiliacs and other blood transfusion recipients, Conley said. Common AIDS killers include a form of pneumonia and rare cancers such as Kaposi's Sarcoma, in addition to other conditions such as the central nervous system toxoplasmosis first documented in the British medical publication, *Lancet*, April 9, 1983 by Conley, Remington, and Dr. Benjamin Luft, then a medical instructor at Stanford and research scientist at the Palo Alto Medical Foundation.

SCIENTIST/ADMINISTRATOR APPOINTED DEAN OF THE SCHOOL OF MEDICINE

STANFORD—

Dr. David Korn, 51, chairman of the department of pathology since 1968 and current chairman of the National Cancer Board, has been appointed dean of the Stanford University School of Medicine.

The appointment announced Tuesday, Oct. 9, by Stanford University Provost James N. Rosse and Vice President for Medical Affairs Lawrence G. Crowley will be effective immediately.

Korn will succeed Dr. Dominick P. Purpura who resigned in June to become dean of Albert Einstein College of Medicine. Crowley headed the faculty search committee for the new dean.

Stanford University President Donald Kennedy and Crowley praised Korn "as an outstanding biomedical scientist, teacher and administrator who understands what makes a world-class institution and who promises to bring a new kind of leadership to the Medical School."

They said such leadership "is needed to meet the present rapid rate of change in the clinical and basic sciences while preserving and extending Stanford's unique strengths."

Korn's appointment coincides with the celebration next week of the Stanford University Medical Center's 25th anniversary and move of the medical school from San Francisco to the Stanford campus.

"Those years have been truly years of achievement in science, clinical medicine and medical education," said Crowley. "But Stanford medical school, like all schools that are part of large academic medical centers, faces new challenges brought about by pressures on society.

"Some of the issues include the increasing scarcity of funds available to support medical education and research, government regulation, and trends revising the way medical services are delivered to the public and paid for."

Korn was named by President Ronald Reagan last summer to serve a six-year term as a member of the National Cancer Advisory Board and a two-year term as board chairman.

He is chairman of the Faculty Practice Program and was the first chairman of the medical school's faculty budget review committee. In 1983-84, he also chaired the committee on research of the University's academic council.

Under Korn, Stanford's department of pathology has achieved distinction for its double-pronged approach: the study of disease and processes involved at the basic level. Korn, who came to Stanford from the National Institutes of Health, recruited top talent in clinical services, and he appointed a cadre of young basic scientists to work in cutting-edge areas of research with strong cellular and molecular emphasis, who have themselves won national recognition for their scientific accomplishments.

Korn's own research is on enzymes that synthesize DNA and are involved in DNA replication of higher organisms.

He completed his internship and residency training in pathology at Massachusetts General Hospital after graduating with honors from Harvard Medical School in 1959.

Korn and his wife Phoebe have three children and live on the Stanford campus.

VOLUNTEERS SOUGHT FOR DRUG STUDY

STANFORD—

Male volunteers ages 18 to 40 are needed for a new drug metabolism study being conducted by the division of clinical pharmacology at Stanford University.

Researchers seek healthy, non-smoking men who are currently taking no medications.

Entitled "The Effects of Acute and Chronic Administration of Ketoconazole on the Hepatic Metabolism of Antipyrine and Caffeine," the study examines the effect of a commonly used antifungal drug, ketoconazole, on the removal of other drugs from the body by the liver. Dr. Terrence Blaschke, division chief and associate professor of medicine and pharmacology, is principal investigator.

Subjects are currently sought for the end of October. They will receive physical examinations and several laboratory tests free of charge. They will also be compensated for their participation.

Volunteers will be studied on five separate occasions (for 48 hours) in the clinical research center at Stanford. Each subject will receive a daily oral dose of ketoconazole, a drug in use since 1977, for four weeks. The study will take place over a five- to six-week period of time. Blood, urine and saliva will be taken at each visit.

For further information or to volunteer, call Marni Brown at (415) 497-5266.

GROUP SUPPORTS RESEARCH TO PREVENT SIDS

Photos available upon request.

STANFORD—

A Milpitas couple who lost their second son 22 years ago to sudden infant death syndrome (SIDS) spearheaded a fund raiser bowling drive which resulted last week in a gift of $5,100 to Stanford, in support of SIDS research.

Howard and Sura Weiner have been donating to the SIDS program at Stanford for about a decade, said Stuart Rawlings, administrator of the Stanford Sleep Disorders Center. They founded the International Guild for Infant Survival of California, Inc., as a parent support group and vehicle for ongoing support to SIDS education and research, he added.

"When we lost our son at the age of two months, there was no information, no research, no education, nothing," said Sura Weiner, an assemblyworker in electronics. Since then, the Weiners and others have been working to increase awareness and research into the problem, and to comfort bereaved families, she explained.

"This was our biggest fund raiser so far, and the credit goes to the many SIDS families and friends who brought in pledges and got involved."

Rawlings said that each year more than 7,000 American infants die suddenly from SIDS, which is believed to be related to infant apnea, in which infants stop breathing for dangerously long periods.

"Every parent's fear is to wake up and find the baby has died," Rawlings said.

Physicians at Stanford recommend that some "near-miss" babies they examine be placed on home monitors, to alert the parents if they should stop breathing while asleep.

For more information about the Stanford SIDS program, contact Rawlings at (415) 497-6601, or write to the Stanford Sleep Disorders Center, Stanford Medical School, Stanford, CA 94305.

ONE—YEAR—OLD LIFELINE GIVES SUBSCRIBERS A SECURE FEELING

STANFORD—

Irma Garden, prone to mild seizures following two operations to remove brain tumors, knows she simply has to push the Lifeline button on her neck chain should she suddenly become ill or incapacitated. By doing so she sets off a network of neighbors and Stanford University Hospital's emergency personnel who will rush to her aid.

Garden is one of about 100 area subscribers to Lifeline, Stanford hospital's emergency response system geared towards geriatric, chronically ill and cardiac patients. Anyone in the Stanford area can subscribe to the system, which is coordinated by the hospital's emergency department, community relations office and auxiliary, the Senior Coordinating Council of Palo Alto and Little House of Menlo Park.

When subscribers push the button, which they can wear on a neck chain or like a wrist watch, they activate a transmitter unit attached to their telephone. This alerts personnel in the emergency department to notify predetermined neighbors. Within seconds, help is on the way.

The system was celebrated for its first anniversary Friday (Nov. 30) with a reception for volunteers, hospital workers and subscribers. It's been a great success, with 28 emergency calls so far, said Joan Naber, a hospital volunteer who is the prime mover behind Lifeline. "It's an outreach into the community to show that Stanford Hospital is made up of individuals who really care about people in the community.

"It brings security to senior citizens who want to live in their homes with their pets and be independent. This way they and their children don't have to worry about them living alone," she explained.

The first 100 units were purchased with a $70,000 gift from the hospital's auxiliary, Naber said. There are always people on the subscriber's waiting list, and Naber hopes to be able to raise funds from the community to purchase more units, each of which costs $500.

"Lifeline is indespensible for anyone living alone," said Helen Donaghey, another subscriber. She successfully used her Lifeline button twice, and needed it a third time. "I had taken it off to go for a walk," she said, "and before I had a chance to put it back on when I came home, I fell." Unable to reach it, she lay on the floor all night until concerned neighbors came looking for her the next morning. Donaghey is staying at Lytton Gardens Health Care Center until she recovers from the fractured femur she received from the fall.

"Lifeline makes you feel like somebody's taking care of you," said Winifred Forse, who also uses Lifeline. "When I'm out, I'm always with people," she continued. "It's just when I'm alone that I need it."

For further information on Lifeline, call Naber at 497-6906 or Sharon Beckham, coordinator of volunteer services, at 497-7424.

HOME CARE DIRECTOR NAMED

Photos available on request if not included.

STANFORD—

Registered nurse Kathryn Janz, 35, has been appointed director of the newly created department of home care at Stanford University Hospital, announced associate director of nursing Lois Welches.

The home care program to help Stanford patients after release from the hospital was approved by the board of directors in June. Janz, also an assistant director of nursing, said she hopes the program can begin serving patients by the beginning of February.

The program will be comprised of teams of registered nurses, home care aides, physical and occupational therapists, social workers, volunteers, and a dietary consultant. Patient care will be based on referring physicians' orders. The program is intended to provide the follow-up help patients and their families need at home in an era of shorter hospital stays, Welches said.

First-time mothers, and parents of infants who have been in the intensive care nursery, are prime candidates for home care, as are many other hospital patients, Welches noted. A hospice service will also be offered as part of the program.

Janz comes to Stanford from consulting positions at the St. Francis Memorial Hospital, San Francisco, and at Self Help for the Elderly, a Chinese community agency in San Francisco, where she helped develop and implement home care programs.

Earlier Janz set up and managed a home care and hospice program at Seton Medical Center in Daly City.

Janz received her bachelor's degree at D'Youville College in Buffalo, N.Y., and her master's in nursing at New York University.

Janz, who noted that this week, Nov. 26 to 30, was National Home Care Week, can be reached at (415) 497-5708.

(ADVANCE) FOR RELEASE AM PAPERS, THURSDAY, NOV. 29, 1984

END OF MORATORIUM ON HEART TRANSPLANTS PREDICTED

STANFORD—

An end of the moratorium on heart transplants in a number of the nation's hospitals was predicted by two physicians writing in the Thursday, Nov. 29 issue of *The New England Journal of Medicine.*

The prediction comes from Drs. Gerald Austen and A. Benedict Cosimi of the Massachusetts General Hospital (MGH), who now believe the procedure can be done in more hospitals because of "important progress in the field."

It was four years ago when MGH trustees, in a well-publicized action, decided against a heart transplant program in the prestigious Harvard-affiliated hospital. "It's clear that cardiac transplantation has now been generally accepted as a therapeutic intervention of proved value," wrote the physicians who are members of the Harvard Medical School faculty.

Most heart transplants up to now have been done at Stanford University Hospital and about half-a-dozen institutions by staffs backed by extensive laboratory research and clinical experience in the field. Stanford surgeons, headed by Dr. Norman Shumway, have performed more than 320 heart transplants, more than any other group in the world.

The authors of the article said their views changed because of "the dramatic success in larger numbers of patients achieved at Stanford University."

This work represented "important progress in the field," they said.

The advances cited include better definition of patient selection criteria, monitoring techniques for rejection and use of new anti-rejection drugs such as cyclosporine.

"The improved results have been striking," Austen and Cosimi wrote.

"The Stanford group," they said, "now projects survival to be 75 percent at two years with cyclosporine immunosuppresion, as compared with 58 percent after conventional immunosuppresion."

But in response to the article, Shumway said, "We know there's tremendous improvement in one-year survival, but we don't know yet what the five-year survival will be. We'll wait and see what are the long-term effects of this medication.

11-28-84 -more-

"Because of the still unknown effects of cyclosporine, not every medical center should jump into the cardiac transplantation field."

Austen had reviewed the status of heart transplantation in cautious terms in a 1978 report in the same journal.

He wrote:

Heart transplantation under certain conditions could be "considered rational and acceptable therapy for a limited number of patients."

But Austen had questioned its widespread use in view of a then anticipated five-year survival rate of 35 to 40 percent.

"The massive allocation of medical resources required to attain this end remained difficult to justify on a widespread basis," he wrote.

This complex issue was later highlighted by the decision of the MGH trustees to declare a moratorium on heart transplants in their institution.

"Currently, there are at least 10 American medical centers with active heart-transplantation programs, and perhaps 15 more, including our own institution (Massachussets General Hospital), are either establishing programs or seriously considering them," Austen and Cosimi said.

Although use of cyclosporine has caused lymphomas and kidney damage in some patients and it should be carefully watched, the drug has been "unusually effective," they said.

Hospital costs for the procedure also have decreased from a mean of over $100,000 to $67,000 per patient, they indicated. The direct economic cost for a nationwide program should be somewhere under $200 million if about 2,000 heart transplants are performed annually. This estimate is far lower than the several billion dollars suggested by previous studies.

"Consequently, an end to the moratorium imposed on heart transplantation at a number of institutions can now be anticipated," they predicted.

The number of heart donors potentially available "appear to be about appropriate," Austen and Cosimi estimated.

But if indications for heart transplants are considerably expanded in the future, there would be a major shortage of donor hearts.

GUIDE INTO 'THE MINDS AND HEARTS' OF THOSE FACED WITH THE DYING

STANFORD—

A book, designed to break the communications barrier between medical professionals and patients on matters of death and dying has been written by Drs. Thomas A. Gonda and John E. Ruark of the Stanford University School of Medicine.

The Journal of the American Medical Association (JAMA) calls it "a major contribution, a guide into the minds and hearts of those faced with the dying." The magazine, *Nursing '84*, picked it as the outstanding book for nurses, and the American Journal of Nursing as its "Book of the Year."

JAMA's reviewer added, "There are even circumstances in which I would recommend it to family members requesting material to understand their situation better."

The book, *Dying Dignified: the Health Professional's Guide to Care*, (Addison-Wesley, Menlo Park, CA., 1984, $28 Cloth $11.95 paper), challenges readers to feel and think their way through the complex interactions which evolve from the moment of a fatal diagnosis to the patient's death and its aftermath.

Gonda is professor and chairman of the Department of Psychiatry and Behavioral Sciences, and Ruark is a Stanford medical alumnus now receiving specialty training in psychiatry at Stanford University Hospital.

"We know that many of our colleagues feel ill-prepared to deal with this difficult area," they wrote. "If our outline of some sensible ways of thinking about death can lessen the uneasiness, our goals will have been met."

Communication problems, Gonda said, start when the doctor breaks the news of a life-threatening illness and the patient responds with a strong expression of emotions.

What to say and how to say it is often a problem, he said, and can be vitally important to an effective caring relationship.

"Earthshaking news, for example, should rarely, if ever, be broken over the telephone," Gonda said. "It should be done in private with all parties seated. The number of relatives invited can be determined on a case-by-case basis, but the presence of at least one family member is useful."

Nov. 26, 1984

-more-

Telling a patient that he has a fatal illness can cause shock or even amnesia for much of what is said after the opening announcement, he said.

The book makes these suggestions:

- Bad medical news should be presented in a straightforward manner with carefully chosen, simple words. If cancer, for example, is involved, the doctor should use "cancer" instead of euphemisms such as "growth," "tumor," or "neoplasm" and "malignancy."
- Breaking the bad news should be followed by silence to allow time for reactions.
- Questions from patients and families should be solicited early and directly, and clinicians should routinely ask if their responses were clearly understood.
- It is not necessary to communicate "everything" during the initial session. Specific details can be given as the relationship progresses and as patients and their families request them.

The authors are critical of doctors who are less than candid. "Withholding vital information concerning the shape of the remaining days of someone's life is difficult to defend."

Communicating with patients effectively prevents mistrust, powerlessness and resentment, Gonda said. Patients with terminal illness face three great fears—the fear of the process of dying, the fear of nonexistence, and the fear of what comes after death.

"Feelings of abandonment are among the most difficult emotions confronting them," he said.

The book presents case histories, some contributed by patients and family members, to illuminate the various points. It explores the psychosocial, cultural, and demographic factors that come into play when people must cope with the reality of death. Other topics cover children's reactions to death, the problem of suicide, and the ethically complex decisions arising in the course of terminal care.

Gonda also heads the Stanford University Medical Center's ethics committee. The group is concerned with such issues as the right of patients to refuse prolongation of life, the allocation of costly treatment resources, ethical issues related to experimentation, and the incorporation of ethics into the medical school curriculum.

Ruark teaches a seminar on problems surrounding death and is the psychiatric consultant to the Compromised Host Unit at Stanford hospital.

STANFORD FACULTY PHYSICIAN WILLIAM WATSON DIES OF CANCER

STANFORD—

William Watson, professor of clinical dermatology, died of cancer Sunday (Nov. 25) at O'Connor Hospital in San Jose. He was 45.

An expert in the field of psoriasis, Watson developed and implemented a day-care program for serious psoriasis sufferers at Stanford University Hospital. He was also an advocate of using large-scale screening programs for detection of skin cancer.

Watson was active in community affairs, including service as a volunteer physician in the Palo Alto Our Health Center and Senior Center. Watson, had lived in Palo Alto until his recent illness, when he moved to his parents' San Jose home.

Except for a one-year appointment at the Downstate Medical Center in Brooklyn, N.Y., Watson had been on the Stanford University Medical School faculty since 1970. During the past year, he continued to maintain his office in the dermatology department.

A native of Glasgow, Scotland, Watson moved to Detroit when he was 10 years old. He received his M.D. from the University of Michigan in 1964 and then interned at Highland-Alameda County Hospital in Oakland before entering a dermatology residency program at Stanford. He served as an Army medical officer with Vietnam service between 1965 and 1967.

"As a physician he was known for his warmth and compassion in caring for patients. As a teacher he was concerned that his students learn to reach out and support patients and their families in periods of crisis," said Eugene M. Farber, chairman of the department of dermatology.

Watson was a Fellow of the American Academy of Dermatology. Among university honors, he received the Henry J. Kaiser Award in 1976 and the Arthur Bloomfield Award in 1982 for excellence in teaching.

Watson is survived by his parents, Willie and Jessie Watson of San Jose; and sisters Mary McNally of Santa Clara and Margaret Bazner of Cupertino.

A memorial service will be held at Stanford Memorial Church at 3 p.m. on Saturday, Dec. 8. Funeral services were private.

In lieu of flowers, the family requests contributions to be made to the William Watson Dermatology Audio/Visual Laboratory for Medical Students, Department of Dermatology, Stanford University School of Medicine, Stanford, CA 94305.

WEIGHT CONTROL COURSE OFFERED

STANFORD—

An eight-week course on weight control is being offered by registered dietitians Kristine Berge and Patricia Kearney at Stanford University Hospital.

"An Enlightening Experience" includes a personalized weight loss plan, low calorie cooking demonstrations and recipes, menu planning, and tips on dining out wisely. Guest speakers will discuss stress reduction, behavior modification techniques, and exercise.

Participants can register for either afternoon or evening sessions, to be held in the north cafeteria dining room. The evening class will meet Tuesdays, Jan. 8 through Feb. 26. The afternoon class will meet Thursdays, Jan. 10 through Feb. 28.

Enrollment for each class is limited to 20 participants. The fee is $300, with a $50 refund if weight goal is achieved.

The registration deadline is Dec. 18.

For further information call (415) 497-5440.

VOLUNTEERS NEEDED FOR DIABETES STUDY

STANFORD—

Volunteers ages 30 to 75 are needed to participate in studies at Stanford University Medical Center examining the link between diabetes mellitus and premature atherosclerosis as well as other abnormalities of fat metabolism.

Non-diabetics are needed, as well as diabetics treated with oral medications or diet, but not with insulin injections. They will be compared, using both standardized meals and glucose infusions to assess responses in blood sugar, insulin, and fatty acid levels.

The study requires that subjects spend two to three days in the clinical research center (CRC) at Stanford, scheduled at their convenience.

Participants will receive, at no charge, a complete physical examination and screening laboratory evaluation, including a glucose tolerance test. "This is particularly of value since occasionally we find an asymptomatic diabetic who was diagnosed by participating in our study," said Dr. Arthur Swislocki, an endocrine research fellow with the CRC.

The studies are conducted under the direction of Dr. Gerald Reaven, professor of medicine.

Interested volunteers should call Swislocki at (415) 497-6973, between 9 a.m. and 5 p.m., for further information.

BOOK CHARGES THAT MEDICINE HARMS PATIENTS: RECOMMENDS REFORM

STANFORD—

A new book published by the Stanford Alumni Association for the general public claims that doctors cause diseases because of systematic errors incorporated into medical practice. The application of these errors to masses of patients results in harm or death to large numbers.

The book is likely to be controversial because it smashes some familiar idols—doctors, hospitals and the medical education system. It challenges medicine's inflated estimate of its achievements, and makes a compelling case for the re-evaluation of many long-established practices.

"I do challenge the validity of much of the substance of current medical practice," its author Dr. Eugene D. Robin of the Stanford University School of Medicine said in an interview. "I realize I am not going to be popular with the medical community.

"But a frank admission of the deficiencies of medicine is timely. It could create a sense of humility for future doctors. We in medicine have a lot to be humble about."

The book, he said, grew out of teaching exercises for medical students and young doctors who support his ideas more than older doctors who tend to be negative. One even went so far as to accuse him of selling out to the enemy—lawyers—because the book might encourage malpractice suits.

"They read into my criticisms a challenge of the validity of what they 'know' to be true," Robin said.

Matters of Life and Death: Risks vs. Benefits in Medical Care (pp. 204, The Portable Stanford and W.H. Freeman, New York, 1984, $11.95 paper; $21.95 cloth), claims that many treatments and diagnostic tests of dubious value are introduced into medicine without proof of risk and benefit. Many studies routinely performed on patients are risky and irrelevant or unnecessary. And this happens not because doctors are acting irresponsibly, but because their training is deficient and has not taught them analytic skills for judging what they do or what they read in the medical literature.

"If General Motors introduces a new car, it must be reasonably sure that the new engine in the car doesn't burst into flames," Robin said. "If it does, the company is held liable. Medicine isn't held to this constraint at all. Almost anything—even the wildest ideas—can be introduced. And they can be tried out on large numbers of patients without any requirement for proving they are safe or helpful."

-more-

11/13/84

These facts are not known to the public, to medical students or even to most doctors, Robin noted. Many of these flaws can be corrected. But while waiting for medicine to address them, "I felt patients themselves could take steps to minimize the harmful impact of medicine."

Robin said patients could:

- learn to view doctors as fellow human beings who are not gods.
- know something about the specifics of medical knowledge and the limitations of medicine and diagnostic tests.
- realize that hospitals can be dangerous and should be avoided unless the illness is serious enough and the hospital has facilities for the needed treatment.
- become active participants in their own care. Patients and doctors are partners in an enterprise in which the patient has the largest stake. Passivity can be bad for the outcome of their disease.
- Get an ombudsdoctor to act as advocate, especially in serious illness or life and death questions.
- limit their doctor visits to that which is necessary.

Robin, a widely respected professor of physiology and medicine, insists his book is not heretical or anti-science.

"I believe the purpose of medicine is to help patients directly," he said. "We need more, not less science in medicine, but it has to be better science and more closely linked to the needs of patients."

That medicine can do harm and good is nothing new, Robin said. What is new is that this potential has increased with the progress of science and technology.

"New technologies have economic benefits for industry, doctors, hospitals and medical schools," he said. "The procedures doctors do have multiplied enormously and this growth has occurred without corresponding changes in the processes by which innovations are introduced and doctors are trained."

Radical mastectomy (removal of the breast) for cancer, for example, was introduced into medicine in the early 1900s. Over the years mastectomies were performed in large numbers of women without being put to any kind of test. In 1955 a Scottish surgeon studied two groups of women with breast cancer in which radical mastectomy and simple removal of the lump followed by radiation treatment were compared. Both groups of patients did well, and the surgeon published his results. But no one acted on his findings until the late seventies when carefully designed clinical trials proved he was correct.

"Meanwhile, millions of women were given a psychologically and physically mutilating form of surgery without alternative," Robin said.

Another example is a test using the Swan-Ganz catheter, a tube "floated' into the blood vessels of the lung to make various measurements. "This test is helpful in a very small group of critically ill patients, " Robin said. "But in most others this test leads to no definable improvement. Despite studies showing the test's benefits to be dubious and complications high, it's used extensively in patients it shouldn't be used."

-more-

"In one study of 46 clinically tested innovations introduced into surgery and anesthesia, 23 were found to be harmful and 23 to be beneficial," Robin said. "If that ratio is typical, the amount of harm medicine potentially produces is truly staggering.

"But if you ask students or doctors about these problems, most of them have never heard of them. We have no system for exposing our mistakes or using them as teaching examples and learning from them."

Medicine's problem of dealing with the flood of technologies cannot be solved by a cutback in new developments, Robin said. "This would be impractical and medicine would remain in its present unsatisfactory state. We must change the way we introduce new procedures by the extensive use of carefully designed clinical trials."

Risk-benefit analysis of new procedures, Robin said, is not a widely used tool because clinical trials are costly and are not regarded as a glamour area of medicine. A center for stimulating and organizing clinical trials could be established under the umbrella of the National Institutes of Health.

Robin said reform must come from medical schools.

"Medical training should lead to the conviction that the primary goal for every doctor is to achieve an improved outcome for patients; that diagnosis and scientific investigation are secondary to the well-being of the patient."

Robin said he didn't write the book with Stanford Mecical School in mind, but his observations and prescriptions are applicable.

"If medical schools are to thrive," he said, "they must come up with creative, unusual contributions and changes in the way they teach clinical medicine. These could be as dramatic as the developments of the past 20 years that made Stanford and other schools leaders in the basic medical sciences."

Medical students, he said, must be taught:

- how to evaluate new technologies to avoid mistakes implicit in the too rapid introduction of untried methods.
- to be alert to diseases caused by doctors and medical procedures.
- to recognize that medical knowledge is not fixed but constantly changing.
- a critical but respectful approach to sciences. They should understand the models used by basic science are often not relevant to patients.
- above all, how to listen to patients and to respect both their wishes and opinions.

"We at Stanford should redefine our clinical mission as one which places us in the vanguard of medical schools trying to improve the training of the next generation of doctors," Robin said. "Unless we do that, the next generation of doctors will repeat the errors of previous generations."

BAGSHAW WINS AMERICAN CANCER SOCIETY MEDAL OF HONOR

STANFORD—

Dr. Malcolm A. Bagshaw, chairman of the department of radiology at Stanford University School of Medicine, was named one of three recipients of the American Cancer Society's 1984 Medal of Honor at the Society's annual dinner in New York Friday (Nov. 9).

Bagshaw received the award, the Society's most prestigious honor, for his clinical contributions to the use of radiation in the treatment of cancer. The other Medal recipients are Dr. Robert Weinberg, a cancer researcher at the Massachusetts Institute of Technology, and Mrs. Forrest Mars of Washington, D.C., a national volunteer leader in the fight against cancer.

As this year's physician recipient, Bagshaw was honored by the Society for his "pioneering studies and distinguished leadership in radiation oncology and particularly for new approaches in the management of prostate cancer."

Bagshaw is an international authority on the use of the linear accelerator against a variety of cancers, including prostate tumors, retinoblastoma (an eye tumor) in infants, ovarian cancer, and mycosis fungoides, a cancer of the skin.

He and the late Dr. Henry Kaplan pioneered in developing techniques to use high energy radiation from the linear accelerator in cancer therapy. Since 1956 when their work began, more than 20,000 cancer patients have received such treatments at Stanford.

Bagshaw has been particularly interested in treating prostate cancer, the second most common cancer in American males, accounting for 60,000 new patients each year and 30,000 deaths. In clinical trials directed by Bagshaw since he joined the Stanford faculty in 1956, more than 900 patients with prostate cancer have been treated, with a 75 percent five-year survival rate, forming the largest group of such patients in the world to have been treated at a single medical center with the linear accelerator.

Bagshaw also has been a leader in studying techniques for enhancing the effectiveness of radiation therapy and in the search for new forms of anti-cancer radiation. He was an early proponent of the use of chemical agents to augment the radiation response, and he led in the early efforts to develop negative pi-meson radiation treatments for deep-seated tumors.

More recently, Bagshaw has directed a hyperthermia clinical research program testing heat in combination with x-rays to destroy tumors.

Since 1960 Bagshaw has directed the division of radiation therapy at Stanford Medical School. He became chairman of the radiology department in 1972, and currently holds the Catharine and Howard Avery Professorship in the medical school. Bagshaw did his undergraduate studies at Wesleyan University and obtained his M.D. degree at Yale University in 1950.

The American Cancer Society Medal of Honor is presented each year "to three outstanding individuals in the field of cancer control: a clinician, a research scientist and a lay person," according to the Society. Previous Stanford recipients include Dr. Henry Kaplan, who received the award in 1972.

HOME TRAINING EQUALS GROUP REHABILITATION FOR MANY HEART ATTACK PATIENTS

STANFORD—

Many heart attack victims hoping to exercise themselves back to health can do so as safely and effectively at home as in group training programs, says a Stanford Medical Center researcher.

"Our research shows that selected patients can achieve the same increase in exercise capacity from training at home as in a group setting," said cardiologist Dr. Robert DeBusk in an interview Wednesday (Nov. 7).

DeBusk cautioned, however, that the key to home or gym exercise is careful screening and supervision of patients to ensure that the program is safe for them, said DeBusk, an associate professor of medicine who directs Stanford Cardiac Rehabilitation Program.

"Our results suggest that of the 600,000 Americans who survive a myocardial infarction (heart attack) each year, as many as 47 percent, or 280,000, may be capable of safely completing three months of home training—nearly five times the number of postinfarction (heart attack) patients currently undergoing group training," said the study which appeared in the October issue of **Circulation**, a journal of the American Heart Association.

Authors besides DeBusk, include primary author Nancy H. Miller, nurse coordinator of the Stanford Cardiac Rehabilitation Program; William L. Haskell, Ph.D., exercise physiologist and clinical professor of family, community and preventive medicine; and Kathy Berra, nurse coodinator of the YMCArdiac Therapy Program in Palo Alto.

The study suggests that with proper encouragement patients are just as likely to stick with a good home program as with a good group program, said DeBusk. In the current study, patients exercising at home had regular telephone contact with the nurse coodinator, and electrocardiographic data obtained during exercise training were transmitted periodically to the research center.

"Some patients find a group setting helpful, but others find it more convenient to do their exercising at home," said DeBusk. "The key to home or gym exercise is careful screening and supervision of patients to ensure that the program is safe for them."

Patients exercised at home on stationary bicycles, while the gym patients walked or jogged, DeBusk explained. In each case patients were encouraged to train for 100 minutes per week within a heart rate range which was shown to be safe during the treadmill exercise testing three weeks after the heart attack, he said.

Earlier studies by these researchers have shown that group training significantly increases exercise capacity between three and 11 weeks after uncomplicated heart attack.

In the most recent study, none of the 66 patients who trained at home or the 61 patients who trained in the group program had exercise-related cardiac incidents, although 15 percent experienced angina (cardiac related chest pain) during their training sessions.

"The safety of training in these patients appears to reflect the success of initial screening and continued surveillance of patients," DeBusk said.

Of 378 persons originally screened for the study, 151 were excluded because of complications, including congestive heart failure, stroke, or obesity.

A total of 198 persons ultimately participated in the study, including 37 control patients who were not evaluated until 26 weeks after heart attack and 34 "no-training" patients who underwent exercise testing three weeks after heart attack but did not participate in formal exercise training.

DeBusk said there were no significant differences in the improvement of cardiac function between the home and gym groups. Also, DeBusk said there appeared to be little further increase in exercise capacity in patients who trained for 23 weeks, compared with those who trained for eight weeks. This was true for patients who trained in either home or gym.

Patients in the no-training group showed less improvement in exercise capacity than those in either exercise training group and the control patients showed the least improvement of all, DeBusk said.

Participants appeared to stick with programs in about equal ratios. For example the home training participants completed an average of 89 percent of their prescribed training sessions while gym participants finished 84 percent of prescribed sessions.

"Despite the support and encouragement provided by fellow participants and medical supervisory staff, nearly half of patients drop out of group exercise training programs within six months after infarction (heart attack). In the present study the support and encouragement provided by telephone contact with the nurse appeared to be as effective as that provided by nurses in a group program in maintaining high-level patient compliance with exercise training.

"The reassurance provided by the use of heart rate and ECG-transmitting monitors may also have contributed to the high level of compliance with the home training protocol," the study said.

The research project was conducted with the collaboration of the medical departments of Kaiser Permanente hospitals in Redwood City and Santa Clara, who referred patients. Group training was carried out in YMCArdiac Therapy programs in Palo Alto and San Jose.

HAYES NAMED ASSISTANT DIRECTOR OF HOSPITAL

Photos available on request if not included.

STANFORD—

Manfred Hayes has been appointed assistant director for Stanford University Hospital effective Nov. 5, announced director Sheldon King.

Hayes will assume administrative responsibility for the departments of dietetics, housekeeping, materials management, security, and telecommunications.

He comes to Stanford from the University of California, Irvine Medical Center, where since 1981 he served as associate director of hospital and clinics with principal responsibility for support services.

Hayes graduated with a degree in business administration from the Boston University School of Management in 1973. He then received an M.B.A. from Wharton Graduate School, University of Pennsylvania, in 1975.

Hayes "brings extensive knowledge and experience in all areas of hospital support services to his new position," said associate director Gerald Moller, to whom he will report.

AUTHORSHIP CLAIMS POSE PROBLEMS FOR JUNIOR RESEARCHERS, OMBUDSPERSON SAYS

STANFORD—

Stanford should develop a mechanism to deal with senior faculty members who insist on claiming authorship inappropriately for research projects, says the medical school's outgoing ombudsperson.

"We believe this problem to be of sufficient complexity and magnitude to merit review by the Ethics Committee of the Medical School or the University office of Graduate Studies and Research," Dr. Allen B. Barbour, associate university ombudsperson for the medical school, said in the report released this week.

The comment was included in a 12-page document detailing his three years as the medical school's pioneer ombudsperson. Between the office's inception under his leadership in September 1981, and his retirement Sept. 1 this year, Barbour noted that his office worked with 236 grievances. The complaints arose from 89 students, 46 residents, 20 post-doctoral fellows, 29 faculty and 52 staff members.

In 1984, Stanford Medical Center had 384 medical students, 421 residents, 432 post-doctoral fellows, 567 faculty members and 1,747 staff members.

Serious problems facing the faculty, who filed 11 grievances in the most recent fiscal year, include disagreements about reappointment, promotion and tenure, as well as disputes about authorship of scientific papers.

Barbour noted several complaints from junior researchers who felt that their principal investigator unfairly claimed credit for projects or published articles.

In an interview he explained that he has talked with about five junior faculty or staff who felt a principal investigator had unfairly claimed authorship for their work.

"But in the ombudsperson's role, we are always seeing only the tip of the iceberg," Barbour added.

Significantly, he said none of the junior researchers agreed to pursue a grievance "nor even allow me to talk with the (appropriate) principal investigator."

In the report he noted complaints were not pursued "mostly because the complainant feared reprisal from the very faculty (member) most likely to insist, sometimes openly, sometimes covertly, on co-authorship which the complainant regards as spurious."

Barbour said, "We do not refer here to the appropriate co-authorship of a principal investigator clearly responsible for the integrity of research done under his or her jurisdiction even though the principal investigator did not conceive the project, do the work, or provide much, if any, supervision."

A neutral investigative body in the medical school might be useful but the problems of having a committee review literally hundreds of papers for appropriate authorship would be difficult, he said.

Nov. 6, 1984

-more-

In at least one case, Barbour said a junior researcher who conceived and then performed most of the work was eliminated entirely from authorship until the omission was called to his attention. In at least one case, the researcher insisting on co-authorship had played no role in securing funding or supervising the research.

While solving specific grievances was important, Barbour concluded that identifying and then attempting to resolve larger issues remained a crucial priority.

"Our capacity to investigate and seek strategic resolution of general problems, in addition to tactical resoluton of individual problems, is an important function of our office," he said in the document.

For example, Barbour pointed to the steady decline in formal grievances from medical students, from 36 in 1981-82, to 25 last year to 14 in the fiscal year which ended in September.

"We believe this to be due to general improvement, stabilization, and student understanding of certain vital forces in student life," including the protocol for choosing and changing clerkships (clinical exposure for students) or financial aid, he said.

Intern and resident complaints had steadily increased from eight the first year to 21 this year.

"Generally speaking, interns and resident are more reluctant than any other group to express concerns, for fear of reprisal," Barbour said.

Improved conditions, including reestablishment of the Committee on House Staff Well-Being, has helped address concerns among interns and residents and may ultimately help reduce the number of complaints.

Barbour noted that new regulations from some government reimbursement patients require faculty members to personally perform procedures rather than working with residents as before. This change, he said, "has encroached on our basic teaching function in some situations. It is hoped that the authorities (government and institutional) can work out a satisfactory resolution of this problem while continuing the same quality care for all that has always characterized Stanford services."

Staff grievances increased from nine the first year to 23 this year, and resolution of complaints by non-academic personnel have been made in close coordination with the Human Resources Group.

Postdoctoral fellows have seen an improvement in their ambiguous status—neither employee nor student—since they have been given institutional recognition under the aegis of Dr. Robert Cutler, associate dean for education. Many of the 20 formal grievances filed in the past three years from this group have involved contract ambiguities and uncertainties arising from this group's unclear status.

Parking complaints have "vanished with the completion of the new hospital parking lots," while recently adopted smoking regulations have produced some questions and complaints which could be referred to the Human Resources Group, Barbour said.

Barbour, a professor of clinical medicine (emeritus), was succeeded Sept. 1 in the associate university ombudsperson for the medical school post by Dr. Kenneth L. Vosti, professor of medicine.

CALDICOTT TO SPEAK ON SURVIVAL

STANFORD—

Dr. Helen Caldicott, an internationally known activist in the nuclear disarmament movement, is to deliver the 12th annual Katharine D. McCormick Distinguished Lecture, 5 p.m. Monday, Nov. 12, in the Fairchild Auditorium at Stanford University Medical Center.

The lecture, entitled "The Politics of Survival," is open and free to the public.

A pediatrician, Caldicott has served at Children's Hospital Medical Center in Boston and on the faculty of Harvard Medical School. In 1981 she was the commencement speaker at Stanford Medical School.

Australian born and educated, Caldicott has been an environmental activist since 1971. She has been credited with encouraging the Australian public to protest—and bring to a halt—French atmospheric testing in the South Pacific. She later worked to inform Australia's labor unions about the medical and military dangers associated with the mining and sale of Australian uranium on the international market.

Caldicott has published two books on the physical and psychological consequences of the nuclear arms race: *Nuclear Madness: What Can You Do?* and *Missile Envy: The Arms Race and Nuclear War*. She was the founder of Women's Action for Nuclear Disarmament (WAND) and has served as president of Physicians for Social Responsibility (PSR).

A reception in the Fairchild lobby will follow her presentation.

The McCormick Lectureship honors Katharine Dexter McCormick, who in 1969 donated $5 million to Stanford Medical School with the expressed wish that it be used "for the encouragement and assistance of women pursuing the study of medicine, in teaching medicine and in engaging in medical research."

McCormick was a co-founder of the League of Women Voters and a vigorous champion of women's rights.

Caldicott will participate in various other events on the Stanford campus Tuesday, Nov. 13, being planned and coordinated by the local chapter of PSR. For further information on these call (415) 497-9060.

JAVITS RESEARCH AWARD GOES TO SIMMONS

STANFORD—

Dr. F. Blair Simmons, professor of surgery/otolaryngology, has received a special research award of almost $1.8 million from the National Institutes of Health (NIH), in honor of Jacob Javits, former New York senator.

The Javits Neuroscience Investigator Awards are designated, at the request of the U.S. Congress, for investigators submitting regular research grant applications for competitive review, who have a distinguished record of substantial contributions in some field of neurological or communicative sciences. They are committed for seven years of support, longer than the typical grant period.

Simmons' grant will support ongoing research with Dr. Robert White, professor and chairman of electrical engineering at Stanford, on the development of cochlear implants to improve the hearing of some deaf patients.

The electronic device is science's attempt to substitute wire for the 30,000 hair cells—each sensitive to a different range of sound—that normally line the snail-shaped cochlea (an inner ear structure) and convert sound transmitted from the middle ear to electrical pulses. Engineers under the direction of White have been working for more than a decade to develop a multichannel model which is hoped to outperform its simpler predecessor in patients with "sensorineural" deafness. Simmons can surgically implant the device to test its effectiveness.

Javits, who now suffers from a neurological disorder called amyotrophic lateral sclerosis, or "Lou Gehrig's Disease," has a record of actively supporting biomedical research, Simmons said.

The awards are given with advice from the National Advisory Neurological and Communicative Disorders and Stroke Council. Simmons was informed of his grant last month by Dr. John Dalton, director, Extramural Activities Program, National Institute of Neurological and Communicative Disorders and Stroke, NIH.

MIKLOS HETENYI, STANFORD ENGINEERING PROFESSOR, DIES AT 77

STANFORD—

Prof. Emeritus Miklos Hetenyi of the Stanford Departments of Civil and Mechanical Engineering was found dead at his campus home Wednesday morning, Oct. 31, apparently of natural causes. He was 77.

Neighbors called police after noticing accumulated mail. Hetenyi lived alone and had apparently been dead about two days.

A native of Hungary, Hetenyi was widely known as an expert in engineering stress analysis. He came to Stanford in 1962 after teaching at Northwestern University for 16 years.

A professor of applied mechanics and structural engineering, he was chairman of the Applied Mechanics Department at Stanford from 1965 to 1969. He retired in 1972.

Hetenyi received his diploma in civil engineering from the University of Technical Sciences in Budapest in 1931, then did graduate work at the University of Illinois before receiving his Ph.D. at the University of Michigan in 1936.

He was a research engineer with Westinghouse for nine years before joining the Northwestern faculty.

Early in his career, he was a bridge designer and group leader on the Danube bridges and worked as a bridge engineer for the Hungarian state railways.

Survivors include his son, John Gilchrist, of Arizona, and daughter, Nancy Jean Palmer, who lives in the Washington, D.C., area. His wife, Jeanie, died in 1973.

Further arrangements pending the survivors' arrival on campus Tuesday.

MEMORIAL SERVICES SCHEDULED FOR DR. ANNE YEAGER

STANFORD—

A memorial service for prominent pediatric researcher Dr. Anne Yeager have been scheduled at 12:30 p.m. Wednesday (Nov. 7) in Fairchild Auditorium at Stanford University Medical Center.

The brief memorial is being planned by the Department of Pediatrics in which Yeager served as a faculty member for the past 10 years.

Yeager, an associate professor of pediatrics, died Wednesday (Oct. 31) of a pulmonary embolism while enroute to the Stanford University Hospital emergency department from her Palo Alto home. She was 45.

Best known nationally for her research leading to avoidance of herpes in newborn youngsters, Yeager was a native of Baltimore, where her parents, Dr. and Mrs. George Yeager, currently reside. She is also survived by a brother and sister.

Private funeral arrangements have been made.

FOR IMMEDIATE RELEASE

SCIENTIST ANNE YEAGER DIES OF LUNG CONDITION

STANFORD—

Dr. Anne Yeager, a prominent pediatric researcher and Stanford University Medical School faculty member for the past 10 years, died suddenly Wednesday (Oct. 31) of a blood clot in the lungs. She was 45.

Dr. Norman Rizk, her physician, said Yeager stopped breathing in a paramedic ambulance enroute to Stanford University Hospital from her Palo Alto home. She was declared dead in the emergency department at 7:45 p.m.

An autopsy to disclose the underlying cause of death was performed Thursday and results were not immediately available. But Rizk said pulmonary embolism, or a blood clot entering the lungs, is usually caused by phlebitis or a tumor and is responsible for about 100,000 deaths annually. Although she had complained of shortness of breath as early as Monday, an examination disclosed no apparent cause and she continued to work and was ambulatory up to the time she left for the hospital, her doctor said.

Dr. Irving Schulman, her department chairman, said Yeager was perhaps best known nationally for her research leading to avoidance of herpes in newborn infants. She also is credited with colleagues for important work on cytomegalovirus, a viral infection that once felled about 7.5 percent of the nation's premature infants. Improved blood donor screening was initiated to conquer this ailment based on her work.

Other research, centering on infectious diseases, included a 1976 study which reported that giving measles vaccines to infants was less effective than waiting until they were toddlers. Because of her work, the recommended age for measles immunization was raised from 12 to 15 months in the United States and other countries.

A native of Baltimore, Yeager graduated from Cornell University Medical College in 1965. She joined the Stanford faculty as an assistant professor in 1974 after four years in a similar position at the University of Colorado Medical Center. She was promoted to associate professor in 1977.

The author of numerous scientific papers, Yeager has lectured widely to both lay and scientific audiences.

She is survived by her parents, Dr. and Mrs. George Yeager of Baltimore, as well as a brother and sister.

Schulman said plans for a memorial service were pending.

FOR IMMEDIATE RELEASE

Editors: California Medical Assistance Commission Hearing is scheduled 9:30 a.m. to 1 p.m., San Mateo County Board of Supervisors Chambers, Hall of Justice and Records, 401 Marshall, Redwood City.

SAN MATEO COUNTY MEDI-CAL MAY BE RESTRICTED TO IN-COUNTY PROVIDERS

STANFORD—

Requiring Medi-Cal patients in San Mateo County to receive medical treatment only in their home county would interrupt longstanding patterns of care for many people, says a Stanford faculty physician.

Dr. James Silverman, chief of staff at Stanford University Hospital (SUH) and professor of radiology, said the pilot proposal by the San Mateo (County) Health Commission "would break up longstanding relationships between patients and their doctors. It would interefere with traditional patterns of care and referral and contribute to a two-tier health system."

Silverman was scheduled to testify Friday (Dec. 21) at 10 a.m. in Redwood City at a California Medical Assistance Commission hearing. The state group is seeking testimony on San Mateo County's request for waivers to administer care for the county's approximately 27,000 Medi-Cal patients.

The county has proposed setting up a public insuring organization to pay for inpatient health care at the five hospitals in the county. Physicians in the county will be eligible to receive subcontracts to care for individual patients.

"Patients who have relied on Stanford or other hospitals in the area for their care—in some cases for decades—will now have to shift to new health care providers and new hospitals," Silverman said. Stanford University Medical Center (SUMC) is adjacent to San Mateo County on the Santa Clara County line.

"We're not saying they won't get the same quality of care with their new doctors and new hospitals. But we do want to point out that a large number of patients will be required by a government agency to change doctors and use a hospital other than the one they have had an ongoing relationship with."

Silverman said about 1,400, or 21 percent, of the Medi-Cal patients in San Mateo County receive inpatient treatment at SUMC.

These figures include about 190 children who receive their inpatient care at SUH or Children's Hospital at Stanford (CHAS).

"We believe it would be traumatic for many of these children to have their care shifted suddenly to new doctors and new hospitals," said Dr. Irving Schulman, a professor and chief of pediatrics at SUH and CHAS.

Dec. 20, 1984

-more-

"The majority of our Medi-Cal pediatric patients suffer from severe chronic illnesses where continuity of treatment is important. For children, returning to a familiar place to find familiar doctors and nurses is an even more important psychological boost than for adults," said Schulman, who was also slated to testify at Friday's hearing in the San Mateo County Board of Supervisors chambers.

The San Mateo Health Commission has estimated that Medi-Cal costs would be reduced $1.4 million out of a total of $43.9 million in 1985 by switching to the new payment system. In its proposal, the commission said the system is expected to "reduce costs by utilizing a combination of spending caps, fiscal incentives and effective management."

The primary cost reduction technique is a burgeoning device called prospective payment, which is being used increasingly in a variety of public and private insurance plans. If costs are less than a preset fee, the hospital or physician keeps the difference. If costs are greater, the hospital or physician must absorb the cost.

Silverman said a majority of the San Mateo County Medi-Cal patients served at SUH come from East Palo Alto, Menlo Park and Redwood City.

"Stanford University Medical Center is located on the San Mateo County line and has long been a significant part of that county's health care community," said Silverman, who is currently studying health care financing during a one-year sabbatical. "Indeed, large tracts of land owned by Stanford University are in San Mateo county. It seems unfortunate for patients in these close-by communities to lose the freedom of choice to use Stanford University Hospital," he added.

The same group of patients, Silverman said, would no longer be able to select physicians outside San Mateo County, including Stanford faculty doctors, independent physicians in Palo Alto and surrounding communities or group providers such as Palo Alto Medical Clinic. These have been longtime sources of care for Medi-Cal patients, Silverman said.

Silverman noted that the San Mateo County plan permits referrals outside the county when local facilities are not available. "This is helpful for patients with highly specialized needs, but it does not address the issue facing the vast majority of patients who may have chronic conditions requiring treatment which may not be urgent but which can be enhanced by the continuity of care of the patient's long-time physician.

San Mateo county has said that the proposed system encourages an ongoing relationship with a physician, since a primary care doctor must authorize in advance all non-emergency care sought by the patient "to dissuade inappropriate self-referrals and to improve quality of provided services since only needed health care will be available to beneficiaries."

The Organized Health System, as the proposed delivery system is called, must be approved by the state Medical Assistance Commission in the form of waivers to the statewide Medi-Cal program. It would take effect six months after approval.

HOSPITAL TEAMS WITH RED CROSS TO OFFER HOME CARE COURSE

Photos available on request if not included.

STANFORD—

A class in home care, focusing on the skills needed to care for a person with a chronic illness, will be offered 9 a.m. to 3 p.m. Saturday, Jan. 12, by two Stanford nurses and a social worker at the Palo Alto Chapter of the American Red Cross.

Initiated at Stanford University Hospital, the course has been offered several times a year since 1980, said Stanford oncology social worker Isabel Walker.

Many participants are friends and relatives of patients with cancer or other illnesses, who want to be prepared to care for the patient at home after release from the hospital, she said.

Others may be nurses or other health care professionals seeking basic training and experience in home care, she added.

Walker and nurses Nicola Eisen and Nadine Nakazawa volunteer their time to teach the class.

Among topics covered are: personal care of the patient, proper body mechanics, recognizing symptoms of illness, supervising medications, comfort measures for patients, and social and emotional aspects of illness.

With the increasingly high cost of health care in hospitals, home health care is viewed as an attractive alternative whenever possible, Walker noted. Moreover, professional home care services are being developed through Stanford Hospital's newly created department of home care.

Family referrals to participate in the Red Cross class may be coordinated by Walker and the nursing staff of the Oncology Day Care Center at Stanford. The endeavor is an attempt to "extend services to the home using existing community resources," said Walker.

"What's most important is that we can reduce the feeling of helplessness," Walker said. "Cancer is a family affair. People cannot have cancer and be left alone."

In 1980, Joan McVicker's daughter Lori, then 18, was treated at Stanford for a form of cancer called lymphoblastic lymphoma. Just before Lori went home, her mother took the Red Cross course. She was trained to give Lori her medications, to take her temperature and blood pressure, to give her bed baths, to monitor her nutrition and to do all the things a home nurse would do.

"Lori had problems swallowing her medications," Mrs. McVicker said. "Every time I gave her a pill, she would choke." The Red Cross taught her how to take two spoons, crush the pill between them, and cover it with apple sauce. Then it slid down easily.

"When I took the course," recalls Mrs. McVicker, of Fremont, Calif., "I felt I was the only person facing a loved one with cancer. I discovered a lot of other people were there for the same reason and that we had a special bond."

The fee for this outreach program is $5 per person or family, and it includes the American Red Cross manual, *Family Health and Home Nursing*. Pre-registration is required through the Red Cross, 400 Mitchell Lane, Palo Alto. Phone (415) 322-2143.

FOR IMMEDIATE RELEASE

THE MOLECULAR BASIS OF VISION

STANFORD—

Aside from the usual complaints about not being able to see as well as we'd like to, most people probably don't spend much time thinking about vision. Yet the mystery of how we see has long puzzled scientists. They know that light comes in the eye and is transformed into signals that proceed back to the brain. But they don't know exactly how this is done. They know that it's with the brain that we "see," but they know very little about how it converts light to the visual images called sight. And they don't know much about how and when the system that allows sight to happen is set up.

Stanford scientists and colleagues all over the world are seeking the pieces to solve the puzzle of vision. They are working in a submicroscopic world, dissecting vision at the molecular level, studying cells and their minuscule components that make up the system. They want to know exactly how the vision system is set up and when in the development process it happens. They want to know exactly how messages about light travel back to the brain and what changes they undergo on the way. And once the messages reach the brain, they want to know exactly how the message of sight is relayed. They don't have all the answers yet. But their findings to date have brought them, and science, much closer to understanding how we see.

Understanding vision would make it easier to study its diseases and congenital defects, such as cataracts and lazy eyes, and to develop improved therapies to overcome them. And it would help scientists understand other similar types of systems as well.

Imagine a television set with one million loose wires. To make it work, it's necessary to figure out how to hook up each wire to precisely the right connection. Substitute the eye for the television and you're faced with the problem Stanford neurobiologist Carla Shatz is working to solve. The young scientist becomes animated as she describes nearly six years' work studying prenatal development of the vision system. She is studying how, during development, all the wires—called nerve fibers in the eye—make the precise, orderly connections that exist in the adult.

"It's sort of a miracle to me that somehow nerve cells can grow along the right pathway, get to the right target in the brain, and then make absolutely precise connections that allow the whole processing of information about sight to take place," she marvels.

She does her research with cats, whose vision system is similar to humans. By raising cats specifically for her work, Shatz can record their development from conception to birth. She looks at the fetuses at specific times during gestation, performing the surgeries in her laboratory's mini-operating room complete with scrub basin, sterile surgical kits and anesthetic devices.

12-18-84

-more-

Early in development, Shatz explains, nerve cells that actually carry the informational messages back to the optic nerve extend themselves by long, narrow shoots called axons to a midway point between the eye and the brain. Once the axons reach this point, known as the lateral geniculate nucleus, they sprout branches like wildly growing trees. The branches in both geniculates are initially from axons from both eyes. Those that don't make what will be the axons' final adult-like connection from the retina to the geniculate disappear. Axons from each eye become separated from each other and persevere only in specific portions of each geniculate.

It's how the nervous system knows which branches to drop and which to keep, resulting in a highly organized and precise system, that has Shatz and other scientists puzzled.

"If we knew this we could also understand why the system does not develop properly sometimes," she says. "We'd be able to explain how the experience of sight affects the pattern of connections in the system. We'd also be able to understand more about how the brain works."

Shatz' work has presented some interesting clues. By injecting eyes with a tracer element, she is able to follow the path of the axons. It seems, she says, that those from the part of the retina closest to the nose always reach the opposite geniculate sooner. Thus, they have time to strengthen their connections and become permanent. Axons from the outer portion of the retina from the other eye arrive about three days later and lose out wherever they encounter the axons that arrived earlier.

What's more, this portion of the vision system between the eye and the geniculate is set up before birth, Shatz has found. It's even capable of working, waiting only for the stimulation of light. Knowing this, Shatz says, it could be possible to alter the system prenatally. Once the system is completely sorted out and working with the stimulus of light, however, no altering is possible.

The portion of the system from the geniculate back to the brain develops in the same way, Shatz explains. The major difference is that the connections are not completely set up at birth. Thus, they can be altered by light. For example, consider a child born with one normal eye and a cataract in the other. If the cataract is not removed as soon as possible, too many of the connecting branches from that eye will disappear, leaving the good eye with more than its fair share. Then, even if the cataract is removed, the affected eye will gain little, if any, vision. This is because the child's vision system and all the connections, including those from the eye with the cataract, have already become permanent. But, if a child is born with two normal eyes, and later on in life develops a cataract and undergoes surgery to correct the mechanics of the system, his sight will improve. This is because all the initial connections were in fact normal.

While Shatz is studying the development of the vision system, Dr. Denis Baylor is focusing on one specific part: the retina. He wants to know exactly how the retina works to transform light, which travels in packets called photons, into electrical signals that proceed back to the brain. The soft-spoken neurobiologist has spent the last 15 years of his career involved with this tiny bit of the eye.

The retina is the light-sensitive layer that lines the back of the eye. It is filled with a sodium solution that bathes about 100 million rods, which are responsible for black-and-white vision, and five million cones, which are responsible for color vision. Both types of cells are long cylindrical structures, except for one side of the cones' outer membrane that folds into many layers. Each rod contains about 1,000 disks stacked like dimes. On these disks and on the cones' folded membrane sit about 100,000 light-absorbing rhodopsin molecules—like the molecules found in brine bacteria that cause the salt ponds of San Francisco Bay to turn red seasonally.

-more-

When light hits the rhodopsin molecules, they instantaneously undergoes a transformation that triggers a series of domino-like steps. Somehow the sodium is blocked from entering the rods or cones, and that blockage generates an electrical signal that can be released to other cells in the retina.

Baylor and his colleagues want to know exactly what these domino-like steps are. Even more, they'd like to learn how the sodium is prevented from passing into the cells. They're working on these questions with probes as small as one five-hundredth the diameter of a human hair. These tools enable the scientists to look at one single cell, or a part of one cell, at a time.

Most likely, they have found, sodium travels into the cells via special molecules that act like ferry boats. Sodium hooks onto molecules outside the cell, and when these molecules pass through the membrane, the sodium pops off. So why, when the light hits the rhodopsin molecules, does the ferry service suddenly come to a halt?

"There's only one way it can work," Baylor explains. "Something is diffusing through the cell, causing the sodium channels to close. There is an internal transmitter substance that relays the excitation from the rhodopsin molecules in the disks to the cell's surface membrane."

In a laboratory just downstairs from Baylor's, structural biologist Lubert Stryer has found a clue to what that transmitter is. The enthusiastic scientist's work has provided a piece of the vision puzzle by finding what may trigger the transmitter that cuts off the sodium flow. Stryer has discovered a protein in the retina that helps explain the first of that series of domino steps.

The change that light-hit rhodopsin molecules undergo must happen to hundreds of molecules to create an interference large enough to actually stop the sodium flow into the cells. This amplification process involves a complex, intricate, biochemical machine, Stryer says. It works not only in vision, but in hormone-triggered cells in other parts of the nervous system as well.

Inside dark rods and cones are low concentrations of calcium and high concentrations of a substance called cyclic GMP (guanosine monophosphate). When light hits the cells, the GMP concentration immediately decreases because an enzyme, activated at the same time, eats it up. As it turns out, the rhodopsin molecule does not directly activate the enzyme. Rather, Styer's protein, called transducin, does the job.

Transducin proteins constantly test rhodopsin molecules by knocking into them like bumper cars at a carnival. As soon as a rhodopsin molecule changes, a transducin protein latches onto it. The protein becomes activated and hurries over to activate the enzyme.

"We have what we think is likely to be the first stage of amplification in vision," Stryer says. "We don't know how the drop in cyclic GMP affects the flow of sodium, although it and calcium are fundamental players. But we now know a lot about rhodopsin, transducin, and the enzyme."

With the knowledge and the highly specialized tools the scientists have, such as a laser about one million times as intense as the sun that experts at Stanford's engineering school developed for Stryer's work, "we have a lot of ideas up our sleeves," Baylor says. "We can now change the internal composition of functioning cells and see how it affects the way the cells work." He and other scientists are also studying the encoding process: how the electrical signals actually represent the information sent to the brain. "This is what we need to learn to really understand how the whole process of vision works.

"There are many interesting years of research coming," he predicts. "There will be fascinating things to work on for a long time." Just as it's difficult to improve the way televisions work without understanding the technology, Baylor stresses that it's difficult to change or improve upon how well we see until science understands exactly how we see.

FOR IMMEDIATE RELEASE

DR. ROBERT CHASE: "THE STATESMAN OF PLASTIC AND RECONSTRUCTIVE SURGERY"

STANFORD—

Cecil Upshaw, relief pitcher for the Atlanta Braves, was walking back to his hotel with two teammates back in April of 1970. In high spirits, having pitched his team to victory over the San Diego Padres that day, the six-foot-six-inch tall-Upshaw jumped up to touch a roof. Suddenly, a surge of pain tore through his outstretched arm. Back on the ground, he looked at his pitching hand to see his ring finger torn almost completely off.

Upshaw's teammates rushed him to the nearest hospital. When physicians looked at his finger, he recalls, they just grimaced. "I went halfway bananas," Upshaw says. "I thought my baseball career was finished."

Upshaw's managers sought expert advice. All fingers pointed to Stanford University Medical Center, where a hand surgeon named Robert Chase chaired the surgery department. If anything could be done to fix Upshaw's finger, the Braves managers were told, Chase would be the one to do it.

That same night, a chartered jet flew Upshaw from San Diego to Stanford, where Chase was waiting. Five surgeries and 68 days later, Upshaw left Stanford, finger and hand intact. And in the first game of the following season, Upshaw pitched four scoreless innings to beat the Cinncinati Reds. After the game, Upshaw sent Chase a telegram.

"I got the victory," it read, "but you deserve the save."

Chase does deserves a save—and a victory as well—in a much larger ballpark. He has played a key position in the field of reconstructive hand surgery, nurturing its development from infancy stages in the 1940s to its present state as a unique specialty and fine-tuned science that includes only about 1,200 surgeons in the United States.

"The importance of the human hand to man's overall function is intriguing," Chase reflects. "It's the hands' anatomical capabilities under the control of a very complex brain that make man unique and different. The idea that it's possible to enhance the quality of one's life by correcting the highly complex, biomechanical device known as the hand through reconstructive measures is especially appealing."

Today hand surgeons can improve, if not correct, any hand deformity, Chase says. Microsurgery—techniques with which surgeons can cut and splice vessels, nerves, muscle, tendons and more with minuscule tools they maneuver while peering through a microscope—and the ability to move entire units including skin with their own blood supply, allow surgeons to transfer, modify and replace just about any part of the hand. Toes become thumbs, thigh muscles move up to the hand, leg skin covers up a palm.

These techniques were not available when Upshaw sought Chase's expert skills. In repairing his finger Chase had to use something called the "island pedical flap technique," in which he rerouted skin with blood vessels and nerves from another finger by tunneling through the palm of Upshaw's hand. Today surgeons would be able simply to sew the vessels and nerves back together without involving another finger. This allows the transfer of parts from distances as great as from the foot to the hand.

"The possibilities have become virtually endless," Chase explains. "Using microsurgery techniques we can cope with any of the deformities that occur within a hand whether they result from injury, birth defect, loss of part due to infection or treatment of tumors, or degenerative disease."

Chase is working towards doing this better and more easily. His latest research project is bringing hand surgery into an era that could easily be mistaken for the stuff science fiction is made of. Chase is digitizing—assigning numerical values—to cross sections of each part of the hand. He's entering all this information, obtained by photographing millimeter-thick slivers one at a time, into a computer. He is then able to call up a three-dimensional, movable image of the hand parts on the computer screen. He can move the parts of the hand, isolate them, or make them larger in order to study them in new ways.

"By animating the hand we can study the relationship of one part to another, and the biomechanics of its function," he predicts. "We'll be able to learn exactly what parts can be substituted for others for surgical repairs. We'll also have the data that will allow us to construct artificial parts that are closer akin to human parts. If we better understand how the hand works, we're better able to duplicate it or substitute for it using robotic devices."

The next big advance, Chase predicts, will be the transplantation of limbs, just as with an organ such as a heart or a kidney. The technology is here, he says, but rejection by the body of the new limb is still a problem.

"Cyclosporine, a drug used to keep the body from rejecting a newly transplanted organ, has brought us closer. But a limb transplant would still be an inappropriate operation to do because it isn't vital to life and the risk of the drugs is too high," Chase explains.

"Although hand surgery isn't life saving," he continues, "it is living saving. We have an aging population. Many people will have disabilities amenable to reconstructive surgery. It really has a lot to do with the quality of the continuing survival of patients. Consider the rheumatoid arthritis patient, for example, who is so severely crippled that he is unable to function well, and then he undergoes surgical reconstruction and subsequently can be more independent. This means a great deal to the patients and to society."

Chase has helped pave the way for many of the advances reconstructive hand surgery has undergone. The need for the specialty surfaced during WWII. Military people with hand injuries were spread around various wards in army hospitals—in neurosurgery, plastic surgery, orthopedics and other units—with the various specialists interested in only one aspect of the injury. It was during this time that the surgeon general, on recommendation of J. William Littler, one of Chase's mentors, established special hand centers. Stanford surgery professor Sterling Bunnell, whom Chase considers the "father" of hand surgery, was chosen as the national consultant to the seven centers for hand surgery across the country.

It was the Korean War that brought Chase into the hand surgery picture. After training in general surgery at Yale's New Haven Hospital, Chase was stationed at Valley Forge Army Hospital in Pennsylvania. The hospital was one of only two hand centers in the country during the war, and Chase went on to become chief of its hand surgery section.

He came to Stanford in 1963 and immediately began building up a reconstructive and plastic surgery specialty section within the surgery department he chaired. He pulled a coup in inviting Dr. Harry Buncke, who is credited as being primarily responsible for developing microsurgery techniques, down from San Francisco to use Stanford's laboratories for his research.

"I was doing my experimental surgery in an old wholesale monkey warehouse and in my garage," Buncke recalls. At Stanford, he says, he had access to the facilities while Chase was able to use his expertise to help establish a microsurgery laboratory.

"I brought down the only diploscope, a two-sided microscope used for microsurgery, in the whole Western United States," Buncke says.

Chase quickly won notice as an exceptional educator as well as clinician at Stanford. "I'm devoted to seeing to it that medical students get a proper opportunity to learn human anatomy, surgery, and skills in overall practice of medicine," says the first holder of the Emile Holman Professorship of Surgery. "I pushed hard for the development of plastic and reconstructive surgery, and I urged a lot of my students to go into the field."

His students responded to the man who has won numerous awards for his teaching skills while at Yale and Stanford, and who counts among his former students several leaders now heading departments of reconstructive surgery at top medical schools in the country.

-more-

"There isn't anybody I know who doesn't like Bob Chase," says Dr. Berish Strauch, chairman of the plastic and reconstructive surgery department at Albert Einstein School of Medicine in New York.

Strauch met Chase at a meeting in 1963. "After listening to him speak for only one-half an hour he impressed me so much I asked him to let me know if he ever started a plastic surgery training program. He called me up two years later out of the blue and said 'come to Stanford.'"

Chase teaches by example, recalls Dr. David Dibbell, chairman of the plastic surgery department at University of Wisconsin. "He nurtured our growth as individuals as well as physicians."

As an individual as well as a hand surgeon, Chase is thought to be quite remarkable. His secretary of 21 years, Grace Lee, knows him very well, she says. "He's one of the kindest and most honest individuals I know. But don't let his easy-going attitude fool you—it's just a front. He's really a persnickity perfectionist," Lee admits.

Chase is at work at "the crack of dawn," Lee reveals. And still, she says she doesn't know how he manages to do as much as he does and have time to spend with his family, which has grown to include three children and six grandchildren. He treats them with the products of one of his hobbies, woodworking. "He made them a Noah's Ark that was just incredible," Lee recalls.

His wife, Ann, Chase holds in special esteem. Without her, he says, none of what he's accomplished would have been possible. "She has been an effective partner in my efforts and has made my career successful."

In addition to his clinical and teaching responsibilities at Stanford, Chase is constantly publishing articles and books about clinical aspects of medicine, as well as about issues within the medical profession. His Atlas of Hand Surgery, the second volume of which was published just this year, is considered the "how-to" recipe book of hand surgery. "Chase is the statesman of plastic and reconstructive surgery," Buncke says.

Chase, involved with numerous national and international professional organizations, has just completed a term as president of the prestigious American Society for Surgery of the Hand.

"I hate it when he goes to meetings," Lee laments, "because he always comes back elected to some position and that means more work."

Chase is involved in education on a much broader scale than that of surgery, or medicine. He serves on university-wide committees, such as one that oversees all faculty appointments and promotions. In 1974, he temporarily left Stanford for a stint as president and director of the National Board of Medical Examiners, which is responsible for testing physicians' qualifications for professional practice.

Lee and Chase have the easy working relationship that is bound to develop after working together for so many years. They yell back and forth at each other in their spacious office suite with an obvious underlying respect for each other.

"His father once told me he never thought he'd amount to much," Lee says. "Maybe that's what drove him. He's a father figure and a role model for his students and colleagues. And his patients, especially children, refuse to have anyone else see them."

It was one such child that Chase treated who marked the beginning of a nonprofit organization, Interplast, through which medical professionals volunteer their time and services to treat Latin America's poor. At 13, Antonio Victorio had already dropped out of school, having been mercilessly teased all his life about the gaping hole in his upper lip. Raised by his grandmother in a small Mexican village, he was convinced there was no hope. Word about his plight eventually reached Chase, who volunteered to correct Antonio's cleft lip and palate. Since Antonio, physicians led by Chase's third resident, Dr. Donald Laub, have followed Chase's example and have performed more than 10,000 corrective operations upon Interplast patients.

Fourteen years after being treated by Chase, Upshaw, now a sales manager for a medical products company in Georgia, remembers the experience in detail. "He was just an absolutely wonderful physician," he concludes. All who know Chase—patients, students, and colleagues—seem to agree.

CPR EVENT COMING UP; VOLUNTEERS SOUGHT

STANFORD—

Stanford University Medical Center is scheduled to be one of seven county sites for "Super CPR Weekend," Jan 12-13, 1985.

Program and registration information will be presented during a 30-minute program on KNTV-Channel 11 at 7:30 p.m., Jan. 2, 1985.

Sponsored by KNTV and the Santa Clara County chapters of the American Heart Association and the American Red Cross, the event is expected to draw about 6,000 participants. All will receive free instruction and certification in adult one-rescuer CPR, cardiopulmonary resuscitation, and instruction in the rescue of choking victims.

The sponsors are seeking volunteers to help with the Super CPR Weekend. Volunteers should call the American Heart Association at (408) 247-8555, or Sharon Beckham, medical center coordinator of volunteer services at 497-7424.

STANFORD PHYSICIAN RECEIVES AWARD FROM VENEZUELAN PRESIDENT

STANFORD—

Dr. Eugene Farber, professor and chairman of dermatology department at Stanford University School of Medicine, has been awarded one of the highest honors given by the president of Venezuela.

Farber received the Order of Andres Bello, First Class, from President Jaime Lusinchi during a Dec. 5 ceremony at the Hall of the Americas, Washington, D.C.

The honor was bestowed on Farber "in recognition of his valiant service during the past two decades in the development of human services in Venezuela, primarily in the field of medicine."

His two most notable achievements, Farber said, related to the development of the curriculum for the newly-established Vargas Medical School at the Universidad Central de Venezuela, and the creation and development of the Institute of Dermatology at the Vargas Medical School.

TEENS OFFERED WEIGHT CONTROL COURSE

STANFORD—

A 12-week course on weight control for teens will be offered, beginning Jan. 24, by the department of dietetics at Stanford University Hospital.

The "Shapedown Program" is taught by registered dietitians, and combines diet, exercise, and behavioral techniques for successful weight control. Sessions are designed to assist teens in taking charge of their own weight management, said registered dietitian Kristine Berge.

Classes will run 4 to 5 p.m. Thursdays, Jan. 24 through April 11. Two parent participation sessions, to help them reinforce their children's efforts, are scheduled for 7 p.m. Feb. 7 and March 14.

Total charge for the program including materials is $150. Registration deadline is Jan. 10.

For further information call (415) 497-5440.

HEAD AND NECK CANCER: NEW TREATMENTS FOR A DEBILITATING MALIGNANCY

EDITORS: This article first appeared in the Fall 1984 issue of *Stanford Medicine* magazine.

STANFORD—

When Edwin "Red" Monroe started losing his voice in 1978, he had a "sneaking suspicion" that something more than laryngitis was wrong, but he delayed seeing a doctor. A year later at Stanford Medical Center, Red's suspicions were confirmed when he learned he had cancer in his larynx. "I accepted it," the crusty 62-year-old tool and die maker recalls, "and decided it had to be mind over matter from then on."

Red was fortunate to reach Stanford, which has a nationally recognized program for treatment of head and neck cancers. The diagnosis launched him on a treatment course that included modern medicine's best proven anti-cancer weapons—chemotherapy, radiation, and surgery. Today, Red has been free of cancer for five years. But not all head and neck cancer patients, even those that get care at Stanford, are as lucky as Red.

Although head and neck tumors comprise only five or six percent of all cancers, they are among the most debilitating of malignancies, says Dr. Willard Fee, professor of surgery and head of the division of otolaryngology—ear, nose, and throat medicine—at Stanford University School of Medicine.

The overall cure rate for head and neck cancer is approximately 55 percent. When detected in later stages of disease, survival rates fall to somewhere between 10 and 40 percent, Fee explains. In those who survive, the tumors affect highly visible and functional parts of the body. "No other cancer leaves such a lasting impact on a patient's appearance and activities," Fee declares.

Not to be confused with brain tumors, head and neck cancers grow in the mouth, throat, face, or neck region, including tongue, cheeks, tonsils, palate, and larynx. The growths and their surgical removal can alter a patient's facial appearance and even more drastically hinder vital functions such as breathing, speaking, tasting, chewing, and swallowing.

The key to effective treatment is early detection, Fee says. But because symptoms include such commonplace complaints as sore throat and hoarseness, many people—like Red—put off going to the doctor. In addition, such cancers are rare enough that they may go undetected, even in the hands of an otherwise skilled family practitioner, Fee adds.

"The average family physician may see one head and neck cancer patient in four or five years, and even an ear, nose, and throat specialist will only see about five cases per year," Fee estimates.

Stanford doctors see about five to 10 new patients each week, all of whom enter treatment through a unique cooperative effort known as the Stanford Head and Neck Tumor Board.

The tumor board, which has been meeting once every week since it began in 1976, permits oncologists, radiologists, surgeons and dentists to work together in developing the best treatment strategy for each prospective patient.

"The success of our tumor board is due to the individuals in it," says Fee. "We are committed to what's best for the patient from start to finish, not what's best for the doctor."

This type of collaborative effort among physicians is important for optimal patient care, adds Dr. Charlotte Jacobs, assistant professor of medicine and director of Stanford's Oncology Day Care Center. At some institutions, the first doctor a patient sees will initiate treatment in his own area of expertise, Jacobs observes, even though consultation might lead to a more comprehensive program of care.

"People become entrenched and think that their way is the only way to treat the disease," Fee adds. Compounding this problem, there are no clear-cut, definitive answers available to guide physicians on head and neck tumor treatment. At Stanford's tumor board meetings, physicians discuss whether to use surgery, radiation therapy or drugs—individually or in combination—on a case-by-case basis.

A new approach is a three-pronged attack against head and neck cancers. Chemotherapy is administered first to help shrink the tumor. Surgery may follow, to remove the growth, and radiation treatments kill lingering pockets of disease.

Red Monroe's therapy followed this formula. Within a few months his cancer was under control. But an unavoidable side effect of the surgery to remove his diseased larynx was the separation of his esophagus and windpipe. This left Red voiceless. Because his mouth and esophagus then led only to his stomach, he had to begin breathing directly through a tracheostomy—a hole carved in his windpipe.

More than half of Stanford's head and neck cancer patients undergo surgery at some time for their disease, Fee estimates. "The secret to good treatment lies not only in removing the cancer completely, but also in reconstructing the damaged area so that the person can reenter society without looking mutilated," he explains. "This takes careful consideration about how to do surgery in such a manner that it will not compromise cure while preserving as much structure and function as is compatible with a decent quality of life."

In addition to prosthodontic work performed by specialty dentists who can fashion new head and neck body parts, Fee and his colleagues also employ ingenious methods for cutting and reconstructing with minimal scarring. They use muscle and skin from the chest to rebuild excised jaw and mouth structures. And as much as possible, they make incisions along the shadowed areas of a person's face or throat.

"Even though our surgeons are excellent," Jacobs says, "some operations can have devastating results. We would like to find an effective way of avoiding surgery whenever possible."

To this end, Jacobs, radiologist Dr. Don Goffinet, and Fee have spearheaded an experimental study testing a drugs-and-radiation-only regimen for certain patients. The pilot study is innovative because all of its patients have advanced tumors that normally would be treated by surgical excision.

Those entering the study receive nine weeks of treatment with two anti-cancer drugs, cisplatin and 5-fluorouracil. Biopsies show that most patients still have signs of cancer after this treatment, and so then must undergo surgery, Jacobs explains. But about one-third of the patients appear disease-free after chemotherapy. These patients forego surgery to undergo state-of-the-art radiation therapy under the direction of Goffinet, Jacobs explains. So far, 20 patients have entered the experimental program. Seven have been able to forego surgery, Jacobs says, and only one of these patients has had a recurrence of cancer.

Jacobs is cautiously encouraged. A conclusive study, however, requires pooled results from hundreds of patients. Because head and neck tumors are relatively rare, however, this can only be accomplished in a multi-center clinical trial by physicians around the country, Jacobs explains. To make this possible, she has been instrumental in establishing a national organization, the Head and Neck Intergroup. "We now have several hundred surgeons, radiation therapists, and oncologists eager to cooperate," says Jacobs, who has been elected the group's chairperson.

-more-

Although treating normally operable tumors with chemotherapy and radiation is a tantalizing experimental program, radiation therapy is not new in the management of head and neck cancers. At Stanford, however, radiation therapy is being molded in new ways. One new method involves implanting tiny radioactive seeds at the tumor site. X-ray bombardment from a linear accelerator alone cannot always control a tumor or kill the tiny pockets of cancer that may be left behind after surgery, explains Goffinet, who is an associate professor of radiology. But placing minuscule packets of radioactive material directly in the cancerous tissue—called "interstitial implantation"—is dramatically boosting cure rates.

In a Stanford study of 28 patients with cancer at the base of the tongue, 14 had surgery followed by X-ray treatment from the linear accelerator. The other 14 were irradiated by the accelerator, then implanted with seeds made from radioactive iridium-192. "Ten of 14 patients with implants are free of disease nearly three years after treatment," Goffinet reports, "while nine of the patients in the non-implant group have had recurrence of cancer." There were fewer complications in the patients with seeds, he adds.

"The fact that we have seen no recurrence of base tongue cancer in patients followed as long as three years is a great advance," says Goffinet. Usually this type of cancer recurs within 24 months after more conventional treatment, he notes.

"The key to this success is in the way the seeds are implanted," Goffinet reveals. In the operating room, the doctors thread thin, hollow tubes through the chin and sides of the neck, penetrating the tongue. The seeds are inserted through these tubes and left in place 40 to 60 hours while the isolated patient rests in a lead-shielded hospital room.

Permanent radioactive seeds of iodine-125 offer another implant approach, he continues. The iodine isotope is safe enough to leave inside the patient, providing a long-term source of low-dose X-rays against the tumor. Iodine seeds have been implanted in more than 100 patients, he says, encapsulated within sutures that eventually dissolve, leaving the radiation sources behind.

These strides in treatment are encouraging to head and neck cancer patients and specialists. But all agree that the biggest advance would be disease prevention by minimizing risk factors and better monitoring of high-risk individuals. "If we could predict those at greatest risk, prevention would become a realistic goal," suggests Dr. Martin Hopp, assistant professor of surgery. Hopp's research is aimed at identifying people in the high-risk category through simple testing.

It is already known that head and neck cancer is more common in smokers and drinkers, particularly those over 50, he explains. Approximately 50 to 60 percent of Stanford patients drink heavily, he says, and 90 percent have smoked heavily at some time.

Carcinogens, chemicals that cause cancer, are thought to play a major role in triggering head and neck tumors. Hopp is focusing on benzopyrene, one of these chemical culprits found in cigarette smoke. Although benzopyrene itself doesn't cause cancer, he says, it is converted inside the body to more harmful substances.

-more-

People have differing levels of one of the enzymes responsible for converting benzopyrene to its carcinogenic cousins, Hopp explains. For each individual, this enzyme's level is under genetic control; head and neck cancer patients are thought to have the highest levels, he says.

"We have developed a test in animals that can detect this enzyme's level, and we are now evaluating the test's effectiveness in humans," he says. "This could enable us to quantify one of the risk factors for head and neck cancer in each individual. Those at high risk would obviously be urged to stop smoking," he comments.

Hopp also points out that some head and neck cancer patients get two or three additional tumors. "High-risk patients could be followed carefully to catch any problems before they progress too far," he says.

"When we treat a patient," Fee says, "we look not only at the person's disease, but consider psychological needs, occupation, finances and family situation."

"All of the treatments are hard, and patients need a lot of personal attention and care," agrees Jacobs. One of the first people they encounter is oncology research nurse Linda Rich Goffinet, who makes herself available and supportive to patients from the moment they arrive at Stanford.

Help in coping with the emotional pains of cancer is also available through a weekly support group led by clinical psychologist Dr. Steven Katz. "This is the cancer you can't hide," stresses Katz. "Patients and families need emotional support in adjusting to changes in body image and personal appearance, eating habits and communication."

Former patients often provide the best help, notes Katz, in demonstrating that a productive, active life is still possible. Red, who has returned to work and still enjoys his favorite hobbies, including hunting, exemplifies those patients who have made successful readjustments.

For Red, the most disturbing aftermath of surgery was the loss of his voice. Although for a while he tried to use a speaking device, Red soon decided that he wanted to talk in a more natural way. So he chose to learn "esophageal speech," a task that took two years of hard work and practice under the tutelage of speech therapists.

In order to use his mouth cavity's resonance to voice words—because he no longer gets an outflow of air from the lungs—Red pushes air into his stomach and then releases it as he talks. His speech, punctuated by unobtrusive burps, is surprisingly normal, though "guttural," he puns with a grin.

A self-professed optimist, Red doesn't regret one moment of the work it took to perfect his new voice. "I never think about it," he says in his distinctive gravelly tone. "I never let this cancer get me down. Oh, right after the operation I felt depressed. But that went away as soon as I could talk to my daughter in Pennsylvania over the phone."

HEAT-RADIATION COMBINATION SHOWS PROMISE IN NEW CANCER TREATMENT METHOD

STANFORD—

Stanford University physicians are testing a new cancer treatment that combines radiation and heat in a unique way.

Eight patients with tumors of the head and neck or colon/rectal cancer have been treated with the experimental technique in the past 15 months at Stanford Medical Center, with some "impressive" results, said Dr. Don Goffinet, associate professor of radiology.

"The early results are encouraging," Goffinet said. However, he cautioned that the combination therapy, called interstitial hyperthermia, needs further testing.

The treatment combines two techniques relatively new to cancer therapy: interstitial implants and hyperthermia.

Interstitial implants are small pieces of radioactive material embedded directly in cancerous tissue. Hyperthermia is the application of heat to tumors.

In the new combination approach, both the implants and the heat are delivered by means of slender, hollow tubes temporarily implanted into a patient's tumor.

Gamma rays emanate from tiny nuggets of radioactive iridium-192 that are placed inside the tubes. Heat is produced by radiofrequency waves pulsed through a metallic grid which coats the outside of the tubes. An insulating sheath coating most of the grid permits researchers to heat only the targeted cancer, sparing healthy tissue.

Side effects have been limited to some localized pain during the heating periods, Goffinet said.

A key element in the procedure is the sophisticated heat monitoring and delivery system developed by research associate Stavros Prionas. Sensors in the tumor relay temperature information to a computer that controls radiofrequency pulses generated down each tube. The computer is set to keep the tissue evenly heated at the selected temperature, Goffinet explained.

The procedure has thus far been tested at Stanford Medical Center in a pilot study of its effectiveness. "We have seen excellent responses in some—but not all—of the patients," Goffinet reported.

12-17-84

-more-

"We still need to determine whether the heat really adds a benefit above and beyond the radiation from the implant," he said.

This should be done, he added, through a controlled trial in which some patients are given heat with implants while others receive no heat. Goffinet said Stanford could be involved in such a clinical trial.

The still-experimental therapy is used in combination with more traditional treatments such as chemotherapy, radiation therapy from the linear accelerator, and surgery, Goffinet said. It is limited to solid tumors that are not too deeply seated in the body for tube placement, he added.

Goffinet conceived the notion of pairing implants and heat in the mid 1970s when hyperthermia began to be applied with promising results against certain types of cancers.

He has developed the techniques with colleagues in Stanford's department of radiology, including chairman Dr. Malcolm Bagshaw, associate professor Dr. Daniel Kapp, radiobiologist Dr. George Hahn, and research associate Dr. Stavros Prionas. Radiological physicists Peter Fessenden and Thaddeus Samulski, electronics engineer Eric Lee, and hyperthermia technologist Allan Lohrback have also been involved.

The tubes used in the procedure were developed in collaboration with Oximetrix Corporation, a Mountain View biomedical instruments company.

Interstitial implants have been used in combination with surgery since the mid 1970s to treat breast cancer and tumors of the throat and tongue at Stanford, Goffinet said. By implanting radioactive seeds directly into a tumor, a dose of lethal radiation can be delivered directly to cancerous cells with less harm to surrounding normal tissue, he explained.

Goffinet wanted to team hyperthermia with implants because heat treatment seems most effective when used in combination with other anticancer therapies. Research shows that heat seems to make cancer cells more susceptible to chemotherapy or radiation, he said.

In the new procedure, patients undergo surgery with general anesthesia to install the nylon-coated tubes in the tumor. Following the operation, the tumor is heated to a temperature of 42 to 43 degrees centigrade (about 108 to 110 degrees fahrenheit) for 45 minutes. Then, the radioactive material is threaded down the hollow tubes to the tumor site. The radiation source is left in place for several days, then taken out. The tumor is then heated once more, and the tubes are removed.

The special hollow conducting tubes, or catheters, used in the procedure are crucial elements, Goffinet said. Now that the technique has been shown to work, Oximetrix Corporation will request approval from the Food and Drug Administration to carry out further testing, Goffinet added.

STANFORD HOSPITAL HAS HOLIDAY PLANS

Editors: The following is a partial list of holiday activities planned at Stanford University Hospital. Please call the news bureau, (415) 497-6911, if you wish to send photographers or reporters to any of the events.

- **Dec. 18:** The Stanford University Medical Center Auxiliary will decorate all Christmas trees in the main medical center and Hoover Pavilion.
- **Dec. 19:** Santa Claus and a magician will attend the pediatrics Christmas party. That same evening, representatives from Hewlett-Packard will visit the pediatrics unit dressed as Santa, Mrs. Claus, and elves.
- **Dec. 21:** Beginning at 9 a.m., Auxiliary members will distribute poinsettias to patients remaining in the hospital through Christmas. This is the group's annual gift to patients.

A local group of Camp Fire Girls will come caroling in the hospital, 5:45 p.m.

For the third year, Don Chudzinski, a Stanford Hospital employee, will play his accordian and lead employees, students and other caroling volunteers distributing 200 red and green balloons (courtesy Looney Ballooney of Redwood City) throughout the hospital. The group, which will include Santa and some elves, will start in pediatrics.

- **Dec. 22:** Jim Rawles and the San Jose State University Choraleers dressed in Dickens costumes will visit the hospital, 7:45 p.m.

Members of the Holiday Project, a San Francisco-based group, will bring gifts to pediatrics patients, both for that day and for Dec. 25. This group has been bringing gifts for several years at Christmas time.

In addition to activities listed above, the hospital personnel department has sponsored several events, including a door decorating contest (decorations go up Dec. 17 and are judged Dec. 19) and holiday caroling by employees Dec. 17 through 21.

Also, retired Teamster Don Hoffman of San Mateo continues to deliver loads of new toys to the children in the pediatrics unit, as well as Children's Hospital at Stanford. A Stanford outpatient recovering from illness himself, Hoffman, 73, took the project on for the firefighters at San Mateo's DeAnza station, "so I could do something nice for other patients." The toys, he says, are donated by the firefighters as well as police personnel, union members, local businesses and San Mateo residents.

"We save the toys Mr. Hoffman brings and give them out to the children on Christmas Day," says Colette Case, recreation therapist. "They're wonderful."

CHROMOSOME BREAKPOINTS LINKED TO ONE

FORM OF CANCER OFFER NEW RESEARCH INROADS

STANFORD—

A chromosome abnormality linked to one form of immune system cancer may provide new clues about how and why such cancers arise, report scientists at Stanford University and the Southwest Biomedical Research Institute in Tempe, Arizona.

Studies of the chromosome abnormality also might someday lead to new treatment strategies for this form of cancer which accounts for four percent of childhood tumors and one percent of adult cancers, the researchers said.

However, the scientists emphasized that the research is preliminary and does not yet offer clinical benefits.

The work, reported in the Dec. 21 issue of *Science* magazine, involves T-cell cancers, malignancies of one kind of immune system cell that helps protect the body against disease.

The scientists studied chromosomes—units of hereditary material found in all cells—from three patients with T-cell cancers. In all three, they found that one region of a particular chromosome—chromosome 14—had broken off and reattached in abnormal configurations.

The finding that chromosome breakage occurred at the same site in the genetic material from different patients suggests that disrupting that chromosomal region is one way of triggering T-cells to become cancerous, said Dr. Stephen D. Smith, associate professor of pediatrics at Stanford University School of Medicine.

"The exciting thing is that we can now study these cancer cells in the laboratory in hopes of precisely pinning down what happens when the chromosome breaks occur," said Smith, who is a pediatric oncologist based at Children's Hospital at Stanford.

-more-

12-14-84

The laboratory studies have just become possible, he explained, because the researchers found a way to grow cancer cells from the patients in the laboratory.

Smith published the report with colleagues Dr. Frederick Hecht, Rodman Morgan, and Dr. Barbara Kaiser-McCaw Hecht of the Southwest Biomedical Research Institute.

Smith said that in studying the chromosome breakpoints the researchers will follow up on some current ideas about how cancers develop.

Recent research suggests that all cancerous cells contain chromsomal abnormalities, which are often associated with "fragile" spots in the DNA. Smith and his colleagues plan to study how the breakpoints they have found relate to fragile points that have already been identified in human chromosomes, he said.

They also plan to study just what goes awry when the chromosome 14 DNA breaks and reattaches in T-cell cancer patients. The chromosome rearrangement might allow T-cells to start producing a protein that stimulates them to boundlessly grow and divide, Smith suggested.

This possibility would mesh with a current hypothesis that has gained favor among cancer researchers. It proposes that overproduction of naturally occuring growth-promoting proteins may be one of several events that lead to cancer. (Uncontrolled cell multiplication is the hallmark of cancer, Smith explained.)

If a growth protein is the cause of some T-cell cancers, then blocking the protein in its misguided growth-promoting mission would provide a potentially new form of treatment, Smith said. This could potentially be acomplished with monoclonal antibodies, the "magic bullets" that can home in on highly specific protein targets in the body.

The research was funded by grants from the National Cancer Institute, the American Cancer Society, and the Leukemia Society of America.

FOR IMMEDIATE RELEASE

ROBOTS MAY SOON AID THE DISABLED AND THE ELDERLY

EDITORS: This article first appeared in the Spring 1984 issue of *Stanford Medicine*. A photo is available on request.

STANFORD—

You are in a hospital bed, recuperating from surgery. Your mouth is parched, and it is painful to move. Water on the bedside table is beyond reach, so you ring the buzzer for help. A few moments later, a soft whirr announces the arrival of the nurse's aide, and a metal hand politely offers you cool refreshment. Suddenly you realize that your helper is a robot. Before you can summon a "thank you," the efficient aide asks if there is anything else you would like, and then moves away to respond to another patient's call.

It's a science fiction scene . . . for now. But in the not-too-distant future, robots will be found rolling down hospital corridors delivering some forms of routine patient care, freeing nurses and other health professionals for more skilled medical tasks, predicts Dr. Larry Leifer, a Stanford professor of mechanical engineering.

Robots may one day participate in flexing stiff joints of patients in physical therapy, bathing elderly people in nursing homes, assisting surgeons in the operating room, and processing samples in medical laboratories, according to Leifer's scenario.

Leifer is head of one of the country's few research centers attempting to integrate robotics technology with patient care. At the Palo Alto Veterans Administration Medical Center (VAMC), he heads a team of medical and engineering researchers who are developing robotic devices to aid the disabled.

The focus of Leifer's Rehabilitation Research and Development (RR&D) team's effort is a microcomputer-directed mechanical arm that manipulates objects in response to voice commands and small physical movements of its operator. The robotic arm project is a unique venture that illustrates, even at this early stage of its development, the potential for robots to help people.

The arm is freestanding and equipped with a two-fingered hand. It extends as far as 18 inches with six degrees of freedom—up, down, left, right, forward and back, with rotations about each of these axes. It has a 58-word vocabulary to which it can respond on command, a special "joystick" that can be used to control its movement, or it can be preprogrammed to carry out a planned sequence of movements.

Its inventors stress that the robotic arm is a tool for replacing lost function; it is not a prosthetic device designed to replace anatomy. But its dexterity could nonetheless help loosen the shackles of paralysis for an estimated 40,000 quadriplegics in the U.S. and assist another 200,000 individuals with severe physical limitations, Leifer estimates.

Rehabilitation devices represent only the front lines of a platoon of robots that could march into medicine in the future. The Japanese already have built and clinically demonstrated a two-armed robot manipulator that can transfer patients between gurney and bed. Some hospitals in the U.S. have launched experimental mobile robot carts that follow preset paths to deliver meals and linen.

"Robots have a potentially rich and complex future in medicine," says Leifer, a serious, soft-spoken man whose sense of humor occasionally flashes through his earnest demeanor. When he talks about his hopes for turning robots into useful tools in medicine, his fantasies can turn an uninitiated listener into a believer.

Leifer envisions robot physical therapists able to help patients build back strength and dexterity. He predicts robot companions that could tirelessly support patients who need help walking. As surgical assistants, robots could apply clamps, fetch materials, or hold and pass instruments for the surgeon. And robot aids could participate in routine tasks such as rearranging pillows, replacing bedpans, checking sensors, and helping patients roll over or get in and out of bed.

Surprisingly, much of the technology needed for such automated medical helpers is already available, Leifer says. The robotic arm his group is using, for example, is a standard model used for light assembly work in industry. The challenge lies in molding these off-the-shelf manipulators into semi-autonomous partners that can sensitively and effectively respond to their human users' needs.

"Our first priority is to improve the link between the human and the robot," Leifer says. "Industrial robots of great complexity are now being designed, but the ability for humans to communicate with them is not being built in. You cannot go up to these robots and simply say 'stop'. You have to be a trained programmer to get them to understand you. I don't want the human user to be enslaved to the robot," stresses Leifer. "The reverse should be true."

In order to shape an effective interaction between the robotic arm and the people it's designed to help, Leifer has collaborated with Dr. Inder Perkash, chief of the spinal cord injury center at the Palo Alto Veterans Administration Medical Center.

"You can't just decide that you want to develop a product for patients without understanding their needs," says Perkash. "That is why the engineers go on patient rounds with us every week."

Leifer adds, "Most companies don't test their products with people until they are already designed and built, partly because it is tricky to introduce new technology so early in its evolution. You have to let people know the experience they are getting is like a shadow of the real thing. But we must know how they respond to the shadow if we are to achieve an excellent end result."

Early models of the robotic arm already have been successfully tested by about two dozen spinal cord injury patients in the VA unit, says K.G. Engelhardt, a technology transfer specialist in the RR&D program.

Because the ultimate aim of the robotic aid project is to help restore independence for quadriplegics—people who are completely paralyzed from the neck down—the device's abilities must be broad-ranging and versatile. Basically, says Engelhardt, there are three types of tasks for the arm to perform: those in daily living, such as brushing teeth or preparing a meal; recreational activities like drawing a picture or playing a board game; and vocational tasks such as turning the pages of a book or opening a drawer.

"But when first presented with the arm, if you ask most paralyzed patients what they want it to do, they say they want a drink of water," Engelhardt comments. And with only about 45 minutes of training, someone can direct the robot limb to accomplish the task, she adds.

First, a voice recognition unit is primed to listen for particular inflections of the user's voice. Then, issuing commands like "up, left, right, open" the user directs the arm's motions in space. The voice recognition unit Leifer's group uses understands commands about 90 percent of the time under real working circumstances. To avoid acting on any misunderstandings, the unit echoes most directives with a voice synthesizer before executing its mission.

Getting close to the glass of water is relatively simple. But coaching the "hand" to close in and grasp the cup without tipping it or permitting it to slip through its fingers is another problem entirely, says Leifer—a problem of autonomous sensory capability and control of force.

"I can get the arm from here to there with relatively little information," Leifer explains, "but the fine motions involved in getting from there to grasping the cup at the right spot with the right amount of pressure may involve 10 to 100 times as much information." Currently, his group is working on perfecting the arm's sensory system and its ability to grip automatically once in the general locale of the object to be retrieved, he explains.

At present, the arm is fitted with optical sensors in its simple two-fingered hand. "This sensory ability is similar to touch, but does not require physical contact," Leifer explains. When approaching an object, the sensors send out a beam of light and gauge distance by measuring the intensity of the light returned after bouncing off the object. It's a workable system, but not good enough, he says. For instance, the gripper would be blinded trying to retrieve an object fallen into a bowl of soup. To improve sensory capacity, future models may incorporate "whisker" sensors that could lightly brush object surfaces, enabling the hand to scan contours in a nearly tactile fashion, Leifer says.

Another problem is mobility. The current model is bolted to a table. "It's good if you want to pick up a book from the table, but not if you need a book from the shelf in the next room," says Brodie Lockard, a Stanford engineering master's student. Lockard, paralyzed from the neck down following a gymnastics accident, is an RR&D staffer improving existing programs and creating new vocational programming functions for the arm.

This spring, the first generation of mobile arms is being assembled using a "reinvention of the wheel" by William La, a member of the RR&D center. The arm sprouts from a cabinet perched atop three of the specially designed roller-wheels. Dubbed "omnidirectional" by the Leifer group, the wheels endow the mobile arm with the agility to negotiate tight indoor spaces. It can move sideways and can turn on a dime; and the unit's 22-inch-diameter figure is small enough to permit it to squeeze through the tightest doorway.

Remote steering of the unit can be achieved through ultrasonic sensors mounted on the back of a person's wheelchair. These sensors respond to a tilt of the head, and users will be able to drive either their own wheelchairs or the robotic aid. In time, the robotic aid will be able to navigate freely in a known environment, Leifer says. The wheelchair user and the robotic aid will also be able to travel along together. Leifer's research group currently is seeking funding to have six of the mobile systems built for advanced evaluation in spinal cord injury—and other—centers throughout the country.

The ultimate goal is to make "smart" robots, says Leifer, controlled by computers that could acquire, store and subsequently use on their own, information from the environment. "When the user says 'get me Shakespeare's *A Midsummer Night's Dream*,' I would like the arm to know where the book is and how to get it without further instruction," Leifer says. A smart machine would also have a more "forgiving" nature, he adds. When unsure of a command, for instance, it would not blindly execute a mistake. Lockard explains the concept simply: "I want the arm to do what I *mean* and not what I say." But such brainy computers—the goal of artificial intelligence researchers around the world—do not yet exist. "Right now, we are barely making robots clever, let alone thoughtful," Leifer says.

-more-

Disabled individuals who currently rely on other people for around-the-clock attendance could gain partial independence emotionally and financially, through the use of robotic aids, says Leifer. "Disabled individuals live at a level of intimacy with a caretaker that most people very rarely choose on their own. They swallow their pride and do it—they have to—but they would prefer to take care of themselves," Leifer says. Robots, at an estimated $6 per hour, could reduce the cost of attendant care which now has a net cost of as much as $15 per hour, Leifer points out.

With the help of robots, elderly people could also maintain more independence and gain more control over their lives, points out Dr. Paul Haber, regional director of programs for the elderly at the Palo Alto VAMC and a strong advocate of the use of technology to aid the elderly.

"We don't want to depersonalize nursing homes. But many nursing home tasks are boring, difficult, unpleasant and demeaning for both patient and caretaker," Haber says. A robot could do things such as toileting, bathing, feeding, transferring, and grooming patients. "And a robot isn't going to come in hung over, or grumpy and abusive because it's quarrelled with its wife," Haber adds.

In other areas of medicine where costs are skyrocketing, robots also could be an economic boon. "Robots will eventually end up costing no more than automobiles," Leifer predicts. "They actually use simpler technology and it requires less material to make a robot than to manufacture a car," he explains.

But no matter how capable and money-saving robots might be, unless they are accepted by those who could make use of them, they are valueless. Because the mechanical arm is the firstborn in this new generation of robots designed to aid patients, Leifer and his group are devoting great time and thought to the process of acquainting potential users with the device. Engelhardt spent over a year devising training methods, and thus far nearly 100 people have been trained, ranging in age from 5 to 72.

"We have to be ingenious in how we introduce robots," notes Haber. "The barriers are formidable, but we know from Larry Leifer's experiments that older people can work with the devices. We must choose and train our initial patients carefully. But we feel confident that the natural advantages of robots will endear them to the hearts of older people, as well as to the disabled," says Haber.

The greatest obstacle blocking introduction of robots into medicine, however, is not lack of enthusiasm but lack of funding, according to Leifer. "It is expensive to carry out the research and development required to turn these ideas and technology into a viable product. The robots may be coming, yet even in industry only a few thousand exist today," he observes.

But Leifer and his group of dedicated colleagues continue to move forward to bring this new melding of medicine and technology to fruition. "While I have stressed the potential for robots in medicine," concludes Leifer, "this is not a panacea. We have asked many questions and certainly don't have the answer for everything here, but at least it's a start."

SURGEON CHASE ELECTED TO HOSPITAL BOARD

STANFORD—

Dr. Robert Chase, professor of surgery and of anatomy, was elected Tuesday (Dec. 11) to the 17-member Stanford University Hospital Board of Hospital Directors.

Chase was elected by the general members of Stanford University Hospital, comprised of university trustees. Stanford University President Donald Kennedy said Chase was appointed to fill a vacancy reserved for a faculty member. He replaces Dr. David Korn, professor and chairman of pathology, who was appointed dean of the School of Medicine on Oct.8. Korn, as dean, remains on the hospital board as an ex officio member.

The Board of Hospital Directors is comprised of community, medical and lay leaders, as well as university faculty and administration to set policy for the hospital under the direction of the general members.

Chase came to Stanford from Yale University in 1963. He served as chairman of the surgery department for 11 years until 1974, when he left Stanford for three years to become president and director of the National Board of Medical Examiners in Philiadelphia. He has won numerous teaching awards, and since 1972 has held the Emile Holman endowed chair in surgery.

Recently Chase was appointed to co-chair the faculty steering committee shepherding Stanford Medical Center's $145 million fundraising effort, announced Monday (Dec. 10).

HEALTH ECONOMIST SAYS RATIONING OF HEALTH CARE CHANGING

STANFORD—

Health care has always been rationed, but new systems of paynment are dramatically changing how medical care gets allocated, a Stanford University health economist says.

In an opinion piece in the Dec. 13 ***New England Journal of Medicine***, Victor R. Fuchs, professor of economics and of family, community and preventive medicine, said "no nation is wealthy enough to supply all the care that is technically feasible and desirable," So society by conscious policy choice should first identify and make available the best modes of treatment. Today, "no one can be certain just which care should be cut," he said.

Fuchs said new modes of payment are placing a larger share of the decision-making burden on individual physicians. New forms of payment, such as Medicare's prospective payment system, are providing lump sums based on diagnosis, not costs incurred.

"The pressure to be more economical in the provision of care will force physicians to make decisions that are contrary to the best interests of individual patients, even though these decisions may make a great deal of sense from the viewpoint of society as a whole," Fuchs said.

He said in the future there must be "more systematic analyses regarding the location of facilities, investment in equipment, training of specialists, and designing of screening programs and treatment protocols" to ensure that finite health care dollars are expended most effectively.

"To the extent that these decisions set the constraints within which individual practitioners function, however, there will be less need for them to ration care to their patients explicitly," Fuchs said in the article. "The commitment of the individual physician to the individual patient is one of the most valuable features of American medical care. . . . For physicians to have to face these (difficult financial) tradeoffs every day is to assign to them an unreasonable and undesirable burden," Fuchs wrote.

Fuchs said rationing of health care is not new. The United States, he said, has always rationed health care, usually based on a patient's ability to pay.

For example, in 1963, the surgery rate for below-average income elderly urban whites was 66 per 1,000 but 86 per 1,000 for those with above-average income persons. By 1970, below-average income persons with assured payment from Medicare received more surgery than their more affluent counterparts.

"Physicians have always practiced within constraints, but as long as the 'rationing' is implicit, it is tolerable," Fuchs said.

NEW TOOL MAY SPEED RESEARCH ON PROSTATE CANCER

STANFORD—

Researchers at Stanford University have developed a laboratory tool that may help in the search for causes and treatments of prostate cancer, the second most deadly malignancy in adult American men.

The tool, a method of growing prostate tissue in cell culture, is not an end in itself but opens the way to learning what factors may cause normal prostate cells to turn cancerous, said Dr. Thomas Stamey, head of the division of urology at Stanford University School of Medicine.

Stamey and his colleague Dr. Donna Peehl reported on the advance in an article in the December issue of the scientific journal *In Vitro*.

The prostate, a walnut-sized gland that produces the fluid components of semen, is the cause of cancer in nearly 30 percent of men older than 50, Peehl and Stamey noted. Because it is a cancer associated with advancing age, it is becoming more prevalent as people are living longer, they added.

Research into the causes of prostate cancer has been hindered by the inability of scientists to grow human prostate cells in the laboratory.

Now, Peehl and Stamey report that they have found a way of growing both normal and malignant prostate cells in the laboratory. "This new ability to culture prostate cells allows us for the first time to look for causes of prostatic cancer at the cellular level," said Peehl.

"Researchers now may be able to find precise differences between normal and malignant cells. Knowing what these differences are may permit us to introduce the powerful new methods of molecular medicine into diagnosis and therapy of this disease," Peehl added.

Surgery and radiation are currently the most widely used forms of treatment for prostate cancer, Stamey said. They are effective, particularly when the cancer is caught at an early stage, he noted. Finding a way to detect the early signs of prostate cancer is one possible benefit of their work, the researchers predicted.

Other potential benefits might include new drugs or other agents that could selectively get rid of the cancer cells while leaving healthy tissue alone, they said.

Cholera toxin is the crucial ingredient that enabled the researchers to get prostate cells to grow in culture, Peehl reported. The toxin stimulates production inside the cells of a substance with an important role in regulating cell growth, she said.

The research was carried out with funding from the Richard M. Lucas Cancer Foundation based in Menlo Park, California.

SURGEON USES NEW TECHNIQUE FOR BLADDER CANCER

STANFORD—

A Stanford surgeon has adopted what has been a relatively unknown procedure in the United States to help male bladder cancer sufferers avoid a urine storage bag and often retain their potency after surgery.

Fuad Freiha, associate professor of surgery/urology, said the surgical procedure he has now performed on three patients at Stanford allows the patient to relieve himself normally through the penis, instead of into a bag mounted externally over the abdomen. During both operations, the patient's malignant bladder is removed.

Freiha said Stanford was the first center in the western United States to perform the procedure.

The operation, which has evolved during the 17 years since it was first performed in France, is appropriate for about 50 percent of male patients suffering from bladder cancer, Freiha said. He estimated about 80 per cent of those receiving the operation are not only freed from the need for an external bladder pouch but retain sexual function as well.

In standard bladder cancer surgery, patients often lose sexual function, because the operation severs the pelvic nerve plexus, which enables males to have erections.

"Traditionally, bladder cancer patients have paid a tremendous price for survival by undergoing urostomies (the operation installing the the bag), which require the constant physical inconvenience of living with an external urine bag, as well as the loss of potency. For selected patients, we believe that the opportunity for survival will be equal but that the quality of life will be far superior," Freiha said in a recent interview.

Dec. 12, 1984

-more-

In recent years, about 50 or 60 persons each year have received urostomies at Stanford University Hospital, Freiha said. Fewer women get bladder cancer than men, and those who are afflicted usually do not require urostomies, he said.

Bladder cancer traditionally is treated with a combination of surgery, radiation therapy and chemotherapy. Until about 10 years ago, treatment protocols produced survival rates of less than 30 percent. Currently, Freiha said, 60 percent of patients whose bladder cancer is detected early enough survive.

The Camey procedure, as the operation is called, was first reported in French-language journals in 1967 by Dr. Maurice Camey of the Central Urological Hospital in Suresnes, France, near Paris.

Few physicians in the United States read French. Freiha, a native of Lebanon, said his knowledge of French helped direct him to the procedure and then study the techniques as Camey developed them.

"With literally thousands of journal articles appearing annually, it is nearly impossible for physicians to keep up with all work directly related to their field," said Freiha.

Freiha said he waited until he believed the operation had been fully developed and then performed his first Camey procedure in September on a 52-year-old man. Two more operations were performed in October and November on men aged 66 and 62, and all three were reported doing well.

Essentially, after the bladder is removed the ileal conduit is sewn back onto the urethra, allowing urine to exit through the penis. In the standard procedure, the conduit is rerouted to an opening in the skin, where it is connected to the external bladder bag which must be removed and emptied regularly.

Freiha said the new procedure offers the slight risk that some patients might be incontinent, unable to control the release of urine.

Bladder cancer primarily affects men older than 40, many of whom "would rather not have a urostomy and are still anxious to continue an active sex life," Freiha said.

Eds: Dr. Freiha may be reached directly at (415) 497-5836.

FOR IMMEDIATE RELEASE

SCIENCE LAUNCHING MULTI-PRONGED ATTACK ON AIDS, EXPERT SAYS

STANFORD—

The battle against AIDS—acquired immune deficiency syndrome—is no longer a blind attack but involves a predictable series of problem solving efforts, a Stanford University infectious disease expert contends.

The first major advance will be a diagnostic test that can detect the AIDS causative agent in blood, "allowing us to gain control over the nation's blood supply within the next year or two," said Dr. Thomas Merigan, professor of medicine at Stanford University School of Medicine.

Also in the next year or two, enough will be learned about the disease and its natural history to recommend more effective personal and public health measures to prevent spread of the disease, said Merigan, George E. and Lucy Becker Professor of Medicine.

Next, researchers may discover ways of interrupting the disease's course, saving some infected individuals from developing the full-blown disease, Merigan predicted.

For example, during the next few years, testing of antiviral agents and experimental vaccines should be under way in people who have AIDS and in high risk groups, he said.

It was the recent discovery of a virus believed to cause AIDS, accomplished by U.S. and French research teams, that has transformed the AIDS epidemic from an open-ended enigma to a well defined medical problem, Merigan said. Medical science has made good strides in understanding other viral diseases and that knowledge can now be put to work on AIDS, Merigan explained. He made his comments in a recent interview and made similar observations in an invited editorial in the Nov. 15 issue of the *New England Journal of Medicine*.

"The rapid association of HTLV-3 virus infection with AIDS soon after the disease was first described is a triumph of today's biologic science," Merigan wrote.

"Unpredictability in the timing of advances of biologic and medical investigation was characteristic of the past," he added. But today, society has the knowledge and scientists to solve scientific medical problems "in the way that we have come to expect of engineers in space exploration and computer scientists in automation," Merigan said.

HTLV-3 virus will soon be proved to cause the deadly illness either when a vaccine against the virus is shown to eradicate the disease, or when the virus is shown to produce the disease in animals, Merigan predicted.

The disease will probably have to be fought on several fronts, Merigan said, rather than through a single treatment or vaccine program. Sensitive diagnostic tests, one or more vaccines, education and public health measures, antiviral therapy, and immune-enhancing drugs will probably all play important roles, he said.

12/12/84

-more-

A diagnostic test capable of detecting the virus' presence will soon be developed that could identify carriers, those who are infected but have no apparent symptoms or complications, Merigan said. Such a test is crucial for preventing transmission of the disease, particularly through contaminated blood or blood products, he pointed out.

As researchers study the natural history of the disease, they may discover why some individuals with HTLV-3 in their blood haven't developed full-blown AIDS. The HTLV-3 virus alone may not be fully responsible, Merigan said. It may be that additional factors—such as other viruses or infectious agents—are required for the full-blown disease to develop, he suggested. If so, fighting these "cofactors" could provide another way of intervening to prevent an infected individual from becoming an AIDS victim.

The first potential vaccines will probably consist of viral coat proteins manufactured through the new techniques of recombinant DNA, Merigan said, rather than from the more risky approach of using a weakened strain of the whole virus itself.

But it is not a certainty that such a vaccination would be protective, he cautioned. A new strain of the virus might be able to get around the vaccination barrier, for example. "Experienced investigators know that the fact that vaccines can be produced does not mean that the whole problem can be dealt with quickly," Merigan wrote. "Don't expect a yes or no answer immediately," he added.

Antivirals used with some success to treat viral diseases such as hepatitis-B are showing some promise, noted Merigan, who is an expert on interferon, a natural antiviral substance produced by the body. "We know that interferon shows some inhibitory action against HTLV-3 in the laboratory," said Merigan. But large placebo-controlled trials in patients are required to test antiviral drugs before any conclusions can be drawn, he stressed.

In addition to interferon, other antiviral drugs are being studied in the laboratory, including nucleoside inhibitors, he added.

Because the HTLV-3 virus is thought to destroy certain cells that make the immune system work, bolstering the body's immune response provides another treatment approach, Merigan said. An "immune-enhancement" drug called interleukin-2, one of the body's own proteins, is being tested in pilot studies of patients with AIDS. It might even be possible someday to resupply the lost immune system cells through transplant procedures, he said.

"Since the government has led in development of vaccines and antiviral agents in the past, it is likely that it will have a critical role in bringing together appropriate investigators and resources from both the academic community and industry," Merigan wrote. "An apparatus capable of attacking this problem rationally is currently in place."

But "the ultimate test of our understanding will be whether we can control this agent in human beings," Merigan observed. "Undoubtedly, the benefits will not come soon enough for all," he noted. "Previous experience with persistent viral infections suggests that there is much work ahead."

ACTING CHIEF OF STAFF INAUGURATES SPEAKERS PROGRAM

STANFORD—

Dr. Michael Eliastam, acting chief of staff at Stanford University Hospital (SUH), told a service club audience Monday (Dec. 10) that the public should begin to reevaluate health care decisions based on new reimbursement systems.

"I want you to understand, that your physicians are under tremendous pressure (from some government or private insurance plans) to get you out of the hospital," Eliastam said in a noontime speech kicking off a new Stanford University Medical Center Speakers Program.

"I want to explain to you how your next health care decision is going to be a little different than it has always been," he said.

Eliastam outlined to about 50 members of the Peninsula Kiwanis Club that many third party payers, including Medicare, are starting to reimburse hospitals and even individual doctors with lump sum payments based on the patient's diagnosis. This contrasts with the traditional practice of reimbursement for treatment provided. In order to survive, hospitals and physicians are under increasing pressure to change traditional patterns of treatment, he said.

For example, Eliastam noted that many Peninsula hospitals, including SUH, are being asked to perform half or more of surgical procedures on a same-day basis, avoiding the cost of an overnight stay. While shorter stays in the hospital may be convenient and the best choice for some patients, Eliastam said that for other patients the shorter stay may be inconvenient and lead to discomfort.

He said it is the responsibility of voters and consumers who might become patients to make their views known to insurance companies and employers buying health plans about what levels of coverage are acceptable to them.

Michael Cowan, the Medical Center's director of public events and organizer of the newly formed Speakers Program, said about 85 nurses, physicians and administrators are available to speak "for the purpose of sharing current information on medical topics with interested groups."

Interested service organizations, clubs, businesses and churches may contact the Office of Public Events, (415) 497-6389.

TRUSTEES OKAY $145 MILLION MEDICAL FUND-RAISING PROGRAM

STANFORD—

A $145 million fund-raising program to support capital projects and endowment for the Stanford University Medical Center was approved Monday, Dec. 10, by the Stanford University Board of Trustees.

Stanford University President Donald Kennedy described the three-year effort to be of a scope similar to the bold move that built the original medical center in the late 1950s.

"It's the largest single resource commitment in the University's history," he said.

Kennedy said $52 million has already been committed toward the goal by private donors, corporations, and foundations.

The University also announced that Dr. Robert J. Glaser of Atherton, chairman; John A. Young of Portola Valley, co-chairman; and Dean Morton of Los Altos Hills, chairman of the volunteer leadership committee, would spearhead the effort.

"Stanford is fortunate to have their powerful leadership," Kennedy said.

Capital projects to be funded by the $145 million effort include a Center for Molecular and Genetic Medicine, $50 million; the New Children's Hospital at Stanford, $40 million; the Magnetic Resonance Center, $5 million; and renovation of the Stanford University Clinic, $2 million.

The program includes also $15 million to be raised toward the $112 million modernization of Stanford University Hospital, now under way. The hospital project is principally financed by a combination of state-guaranteed low-interest bonds, hospital reserves, and private gifts.

Other fund-raising goals include support for professorships, $10 million; junior faculty positions, $10 million; postdoctoral fellowships, $2 million; graduate student fellowships (M.D., Ph.D., and M.D./Ph.D.), $7 million; and medical school programs, $4 million.

The medical center will continue present efforts to raise an additional $20 million a year in gifts to support ongoing activities. Gift support for the medical center in 1983-84 totalled $30 million, Kennedy said.

Glaser is director of medical science of the Lucille P. Markey Charitable Trust. He is former president of the Henry J. Kaiser Family Foundation and has served as Stanford vice president for medical affairs and dean as well as acting university president. Young, a University trustee, is president of the Palo Alto-based Hewlett-Packard Co., one of the nation's largest computer makers. Morton, executive vice president and chief operating officer of Hewlett-Packard, serves on the Stanford University Hospital board of directors.

"We face major commitments and we have developed solid proposals for these ventures," Kennedy said. "They are exciting, but they are also expensive, and hardly free of risk.

Dec. 11, 1984

-more-

"We have drawn on people we know and respect to help shape our future. But in the end it is this faculty that must convert magnificent opportunity into reality and define the future — by its energy and convictions — and its willingness to accommodate gracefully differences in views."

"The plan is to raise the money in new gifts and pledges by 1987," explained Vice President for Medical Affairs Lawrence G. Crowley.

"The goal is to encourage, indeed catalyze, further basic biomedical discoveries and to transfer this rapidly increasing knowledge into new methods of prevention, diagnosis, and treatment of human disease. It is our responsibility, not only to Stanford and our supporters but to society, to live up to our potential."

Another objective is to consolidate patient care programs (for adults and children) at the main center.

"Centralization will improve the quality of care, prevent duplication of costly technology and talents, and stimulate efficiency and cost containment," Crowley said.

Children's Hospital at Stanford, staffed by faculty physicians, is located a quarter mile away from the main center. Its location has posed serious inconvenience for patients and staff alike. In addition, transporting acutely ill patients by ambulance back and forth from the center adds to costs.

Stanford University Hospital, which operates the 150-bed Hoover Pavilion near El Camino Real, faces similar problems because of the distance separating the two. While there are no immediate plans to close Hoover, modernization of the hospital is essential before Hoover beds can be moved to the main center.

* * * *

Details on the fund-raising organization and volunteers follow:

In addition to the community leaders, the fundraising governing committee includes Kennedy, Crowley, Stanford Hospital Executive Director Sheldon S. King, Stanford Medical School Dean David Korn, and Henry Riggs, university vice president for development.

Other committee members are Robert Chase, professor of surgery and anatomy, and Eric Shooter, professor and chairman of the department of neurobiology, who will co-chair the faculty steering committee. Alfred P. Spivack, a Palo Alto physician and clinical professor of medicine, will head the 10-member steering committee of the community physicians fundraising task force. As members of the clinical faculty and medical staff, community physicians have pledged to play an active role in fundraising for the hospital modernization.

University staff on the governing committee are Bruce Hinchliffe, university director of development, and John Ford, director of medical development.

Faculty members who will head efforts for specific program components are:

James Mark and Saul Rosenberg, hospital modernization; Bruce Parker and Philip Sunshine, New Children's Hospital at Stanford; Korn, Paul Berg, Ronald Levy, Hugh McDevitt, and Irving Weissman, Center for Molecular and Genetic Medicine; and David Clayton and Thomas Merigan, endowment.

An advisory committee, headed by David Prince, has been appointed to review and recommend programs for the Magnetic Resonance Center.

ADOLESCENCE: BOYS AND GIRLS GROWING

This story first appeared in *Stanford Medicine* magazine, Spring 1984 issue. Photos available on request if not included.

STANFORD—

They're injured and killed by automobile accidents. They suffer increasingly from eating disorders. They're often depressed and suicidal. And the females are smoking more cigarettes than ever.

"They" are teenagers. Despite a longstanding belief that youth is the healthiest time of life, teens are no more or less healthy than other segments of the population, says Dr. Iris Litt, director of adolescent medicine at Stanford University Medical Center and Children's Hospital at Stanford (CHAS).

The first real opportunity for health assessment of teens came in the late '60s and early '70s when drug abuse, venereal disease, and unwanted pregnancies reached alarming proportions prompting governmental, parental, and medical attention.

Since then, intrigued professionals have uncovered health issues that affect teens, and they have attempted to define ways in which the health care community can better respond to their needs.

"One of the major findings," Litt says, "is that many problems of teenagers are not reported." That's because ongoing, regular medical care for teens is not viewed as necessary by many parents, physicians, or by teens themselves.

When they do come for a medical visit, most healthy teenagers and their parents are concerned to know if they're "normal." Boys question their height; girls wonder about menstruation.

Puberty can be bewildering for boys and girls who don't understand what is happening to their bodies. To ease the transition into adulthood, Litt's colleague Dr. Paula Duke (who has since left Stanford) offered pre-puberty education classes through the Palo Alto Unified School District and CHAS to boys and girls ages 10-12 and their parents.

"Children need information about changes that are going to happen before they happen. What we need to stress is that there is a very wide range of normalcy," says Duke, who participated with other medical and nonmedical specialists at Stanford's Center for Youth Study. The group pools informational resources to research the interaction between the biological and social development of teenagers.

"Everyone turns out fine in the end. Our research is aimed at finding ways to intervene that might lessen the pain and scars along the way," Duke says.

Topics such as masturbation, weight gain by girls, and breast tissue development by boys are often very much on the minds of young teens, even as they hesitate to ask questions, she points out. "There are lots of misconceptions and myths to dispel."

If parents and kids can talk about emerging sexuality early on, Duke says, they're more likely to be able to discuss interactive sex when the time comes. Studies show teenage sexual activity is a very gradual process, Litt says. Sexual intercourse, if it happens between teens, is "very far down the line."

Adolescents suffering from physical deformities or even paralysis need special attention paid to their often unvoiced questions about sexuality. Paraplegics, for example, need to understand that sexual gratification is possible without intercourse.

Because teens often assume the doctor can tell all through medical examination, confidentiality as well as adequate communication become important issues. "Teens want to protect their parents from upsetting information," says Litt, "and from information that might get them into trouble." Still, getting both perspectives about a problem is often revealing and necessary, she adds.

At the same time, teenagers think that if there's anything of concern, the doctor will automatically find out and say so. Thus, girls may seek birth control because they fear they're pregnant and figure if the doctor says nothing it must not be so. Or they fear they're sterile and seek the same silence, which they interpret as reassurance.

Physicians must be aware of these patterns and take the initiative, Litt says. "We can raise issues in nonthreatening ways by pointing out that other kids sometimes have certain questions, or by describing the various services available."

One of the doctor's prime jobs, she explains, is to educate teens about their bodies and prepare them to become wise consumers of health care. This means not only examining them, but teaching girls to examine their own breasts and boys to examine their scrotums for early detection of malignancy. "We should also get them thinking about what they expect from the doctor and how to choose one. And we must encourage them, above all, to ask questions."

With a problem as pervasive as automobile accidents, Litt says, it is incumbent on physicians to get involved. "We can do problem-solving with our patients, by asking them what they'd do if they knew they shouldn't drive home from a late party, whether they'd ever consider calling their parents or a friend, and under what circumstances."

She encourages pediatricians to see patients throughout their teen years. "All of our training has been developmental in approach, we've seen the kids grow up, and it surely helps us to understand their behavior. The best doctor for any teenager however, is the one the teen feels most comfortable with."

Other major medical problems of teens include sports injuries; alcohol and drug abuse; infectious diseases such as mononucleosis, Rubella or German Measles, gonorrhea and other sexually transmitted diseases, tuberculosis and toxic shock syndrome; malignancies such as Hodgkin's disease and testicular cancer; and among lower socioeconomic groups, violence and homicide.

Some adult health problems can have their origins during adolescence as well. These include hypertension, high cholesterol, and cancer of the cervix. Epilepsy can show up in the teen years, as can lupus. Whereas most congenital disorders are diagnosed earlier in life, some abnormalities such as scoliosis and reproductive tract problems don't show up until puberty.

"We're also seeing more teens who wouldn't have survived past childhood without modern medical treatments," says Litt. These patients have undergone treatments such as cancer chemotherapy, kidney transplantation, and open-heart surgery. In treating them, physicians must consider important teenagers' issues: achieving separation from parents, building a capacity for intimacy, and developing a positive self-image.

-more-

Sometimes, Litt points out, perspectives get confused. "We've seen teens with serious diseases care most about getting rid of acne." But child psychiatrist Gregory Fritz, who's been studying how young people readjust to daily life after conquering cancer, feels that many teenagers who have battled death know more about life than their peers.

"They still worry about football games and get shy at dances. But when you talk to them seriously, they seem philosophically closer to adults and more mature than other kids."

Fritz is one of a growing number of professionals eager to expand research into problems of adolescence—research for which funding is scarce.

Meanwhile Litt points out that adolescent medicine is not and should not be a clinical specialty. "In this country there are about 40 million people between 10 and 21, and about 700 teen specialists. Their proper role is to educate other professionals and to serve as leaders of the field in academic settings."

Special services for special people

Stanford Medical Center and CHAS offer a variety of programs tailored to teens.

While treatment is preferred on an outpatient basis, special facilities at both institutions house inpatient children and adolescents. CHAS and Stanford University Hospital's pediatrics unit are in the process of being consolidated into the New CHAS at a cost of $40 million.

"The new facility will allow all our hospitalized teens to be together. We feel it's important for teens to share the hospital experience with others their own age," says Litt, an associate professor of pediatrics.

Issues important to adolescents and those who care for them underlie the services offered. These issues include:

- Eating Disorders—The eating disorders clinic at CHAS offers a unique interdisciplinary approach specifically designed to treat both underweight and overweight teenagers through a team effort by nutritionists, child psychiatrists, and adolescent medicine specialists.

The clinic sees obese teens as well as patients with anorexia nervosa, a disorder in which victims are obssessed with thinness to the point of starving themselves, and bulimia, the binge/purge syndrome. Stanford's behavioral medicine clinic is also available to such patients 18 and over, offering inpatient and outpatient psychotherapy, physical therapy, behavior modification, and nutritional guidance.

Obesity in the teen years has far-reaching implications because it impacts the teen's sense of worth. It is also a risk factor for hypertension and obesity in later life. In addition to the CHAS clinic, a summer weight-loss day camp for overweight teens is offered at Stanford by psychologist Mary Southam. "We introduce the kids to healthy eating and exercise habits, and encourage them to take charge of their own weight management," she says.

- Stress—Psychiatrist Hans Steiner runs the psychosomatic inpatient service at CHAS. He is convinced that in teens stress influences both the onset and the course of illness, such as with diabetic episodes and bronchial asthma attacks. He has developed a test to help predict adverse symptoms that he hopes may be used to help prevent anorexia nervosa.

- Family relationships—"Our society has characterized adolescence as such a worrisome time that parents enter this phase with lots of fears. They tend to focus on the negatives," Litt observes. "Kids haven't heard the positives enough from their parents. Physicians can play the role of facilitators by asking about the good qualities. We can also reassure parents by pointing out the reasons for a teenager's rebellion, reminding them it doesn't last forever, and helping them maintain their self-respect."

-more-

Litt says adolescence provides an opportunity for parents to witness that their basic values have been passed on. "Excessive monitoring of behavior can be misconstrued as mistrust." Excessive hovering, she says, may stunt personality growth in areas of self-confidence and independence.

- Pregnancy—The media image of the pregnant teenager craving a living teddy bear is inaccurate, says sociologist Nancy Moss, who researched perinatal risk behavior in San Jose adolescents with Dr. Paul Hensleigh of Stanford's gynecology and obstetrics department.

"These girls are trying to take steps to make things work in the face of really big problems," Moss says. Most tend to focus on practical and educational plans, having come from turbulent, low-socioeconomic family backgrounds.

There are increased medical risks in teen pregnancies. Thus, one of the biggest concerns is delay in prenatal care. Health care professionals, Moss says, need to provide pregnant teens with information about adoption and abortion options and be more active in supporting their various needs, for the sake of the babies as well as the mothers. Infants born to teenagers are more likely than others to become victims of child abuse, Litt says.

Smoking and drug and alcohol abuse are commonly found among pregnant teens, but may be modifiable behaviors, Moss says. Many teens view pregnancy as an opportunity to "start fresh" and build stability into their lives. Social support and continued school attendance appear to make a difference. The fathers need guidance, too.

One pregnant teen in Moss's survey commented: "If I had a teenage daughter . . . I'd ask the principal if we could have a class for girls to explain to them the things you can do instead of going through all the hurt and pain, giving the baby up or stuff like that . . . You have to teach the girls about birth control if they want it, how to take care of themselves, and how to talk to their parents."

- Medical care compliance—While working in juvenile detention facilities, Litt noticed that some teens indiscriminately abuse drugs, yet others won't take medications prescribed for them. She realized that both behaviors were a form of rebellion. "Compliance seems to correlate with autonomy: making one's own appointment, accepting one's own prescription, paying one's own bill," she says. "A good self-image leads to better compliance.

"Unfortunately, the stereotype of the noncompliant teen can influence medical treatment," Litt says. Whereas an adult may receive medication, a teen will often undergo surgery simply because the doctor fears noncompliance. "Yet teens are no different from adults in this respect. About half comply and half don't."

"Teenagers trust doctors more who accept them as adults than as little kids," observes a 15-year-old patient. "Teenagers should be treated more like adults in order to act like them. If they're treated like little kids, then that's how they'll respond."

GRANTS SUPPORT DIABETES RESEARCH

STANFORD—

The American Diabetes Association (ADA) in 1984 granted research funding support to two faculty physicians at Stanford University Medical Center.

Dr. Merton Bernfield, professor of pediatrics, received a two-year national research award of almost $25,000 for his study of birth defects in diabetic mothers' offspring.

Dr. Fredric Kraemer, assistant professor of medicine, received a $25,000 national research award for his study on the high incidence of heart disease among diabetics.

Bernfield is investigating causes of the increased incidence of severe birth defects, particularly lower spine abnormalities, in children of diabetic mothers—with an eye towards possible prevention. He and his colleagues hypothesize that the causes lie in abnormalities of diabetes in a particular group of molecules.

Kraemer hopes to find reasons for the frequent development of atherosclerosis in diabetics, which is responsible for their leading causes of death: heart attacks and strokes. His goals include determining whether the process leading to atherosclerosis can be corrected with improved glucose control. Ultimately he hopes to help in the development of improved therapeutic approaches to the treatment and prevention of atherosclerotic complications in patients with diabetes.

In 1984-85, the ADA said it plans to spend about $2.8 million on national research grants.

NEW DIVISION FOCUSES BIOTECHNOLOGY ON DISEASES OF THE THIRD WORLD

STANFORD—

A new "geographic medicine" division at Stanford University Medical School is aiming the most up-to-date biotechnology at diseases of the Third World.

Formed this fall, the new division is one of only a few in the United States to apply advanced molecular and genetic techniques to health problems of developing countries, said Dr. Gary Schoolnik, the division's chief.

"By committing new resources and technology toward finding solutions for medical problems largely ignored by Western medicine, we have the potential for bringing new aid to a large portion of the world's people," said Schoolnik, an assistant professor of medicine and of medical microbiology.

Although rarely seen in the United States, diseases such as malaria, schistosomiasis, and sleeping sickness maim and kill millions of people, he explained.

Even diseases considered mild in developed countries often turn deadly in developing nations, such as diarrhea which is estimated to kill five to 15 million malnourished children each year in the Third World, Schoolnik added.

Researchers in the division will use the new techniques of molecular and genetic medicine to study the viruses, bacteria and parasites responsible for some of the most serious infections found in developing countries.

By finding the genes and molecules these organisms use to make people sick, the researchers can then develop vaccines, drugs or other agents such as monoclonal antibodies, that should be useful in prevention, diagnosis and treatment of the diseases, Schoolnik said.

Faculty members of the new division are already conducting molecular and genetic studies of the organisms that cause the deadly liver disease schistosomiasis, African sleeping sickness, diarrhea, cholera, gonorrhea, and fungal diseases endemic to South America, he noted.

12-10-84

-more-

Collaboration with researchers in the Third World will result in "on location" testing of potential drug or vaccine products, Schoolnik explained. Affiliations with health workers in South America, Bangladesh, and Kenya are under consideration, he added.

Medical training and clinical care will also be important activities of the new division, Schoolnik said.

The overseas affiliations could permit students and researchers to study and train abroad as well as allow foreign researchers to train at Stanford, Schoolnik said.

The division's clinical programs will center on two clinics to be established within the next few years, Schoolnik said. One clinic to be located at Stanford's affiliated hospital, Santa Clara Valley Medical Center, will treat Third World diseases which are showing up in the U.S. among refugees and immigrants from such areas as Southeast Asia, Mexico and Central America.

A traveler's clinic will be established in the next two or three years at Stanford Medical Center, where travelers to Third World countries could receive pre-travel information and preventive care as well as treatment on return. "A traveler's clinic would serve the needs of this area, which includes a lot of business travel generated by Silicon Valley," Schoolnik observed.

The new division is affiliated with the departments of medicine and medical microbiology at the medical school, Schoolnik said.

Current faculty members in addition to Schoolnik include Dr. Paul Basch, professor of family, community and preventive medicine and of medical microbiology, whose research centers on schistosomiasis; Dr. John Boothroyd, assistant professor of medical microbiology, who studies the parasite that causes African sleeping sickness; Dr. Stanley Falkow, professor and chairman of medical microbiology, who studies bacterial diseases such as diarrhea and venereal diseases; Dr. Harry Greenberg, associate professor of medicine, whose research focuses on the viruses responsible for most childhood diarrhea deaths; and Dr. David Stevens, associate professor of medicine and chief of infectious diseases at Santa Clara Valley Medical Center, who studies fungal diseases.

The new division is distinct from a $1.5 million parasitic disease research program in Stanford's department of pharmacology, recently funded by the MacArthur Foundation, Schoolnik noted.

First priorities of the new division are to seek new sources of research funding and training grant support, Schoolnik said.

Other medical schools with basic research programs on diseases of the Third World include Johns Hopkins University, Western Reserve University, Tufts University, and the Universities of Virginia and Washington, Schoolnik said.

CHILD SEXUAL ABUSE: PREVENTION THROUGH EDUCATION

STANFORD—

Physicians can play a vital role in preventing and stopping child sexual abuse, which is increasingly affecting younger children and is more often than before occurring within a family setting, a specialist told pediatricians and other professionals at Stanford University Medical Center Friday (Dec. 7).

Current statistics show approximately one out of four girls and one out of six boys are abused sexually before the age of 18, said Evelyn Schreck, training coordinator with the Child Advocacy Council of San Mateo and Santa Clara Counties. The onset of abuse is commonly between the ages of 6 and 8, though many children are abused before they reach 5, she said.

Schreck said responsible adults, including physicians, should be on the lookout for major indicators of abuse. These include knowledge about sexual activity that is inappropriate to the child's age, or an acting out of certain sexual behaviors at too young an age. Most young children cannot describe or act out behaviors they have not experienced, she explained.

Schreck spoke at the department of pediatrics grand rounds, a weekly seminar for physicians.

"Children need to know that there is no way we will allow an adult to continue hurting them after they tell us," Schreck said. They also need to know that being abused is never their fault, and that if the abuser is someone they love, he or she can probably be helped rather than punished forever.

Besides the physical signs of abuse familiar to physicians, there are often sleep disturbances including nightmares and bedwetting, new or strange fears, changes in ways the child relates to teachers and other adults, irritability, and sexual promiscuity possibly leading to prostitution in the case of older victims.

At least 80 percent of offenders are known to their child victims, Schreck said.

"We can't just warn kids about strangers, like in the past." Now they must be warned about inappropriate or "bad" touching (versus "good" touching such as a parent's hug goodnight) by any adult, including people in their own home or neighborhood.

-more-

The closer the tie, Schreck said, the more power an adult has to abuse a relationship with a child.

Schreck provides in-service training to law enforcement and medical professionals required by law to report suspected abuse cases.

Physicians are often asked to determine the validity of accusations between parents in bitter divorce and custody cases. In such situations, it would be wise first to simply talk with the child alone, Schreck said, out of "coaching" range of either parent, and to observe the child's manipulation of "anatomically correct" dolls—which are commercially available.

She predicted future legislation to make it criminal for an adult to accuse falsely of sexual abuse.

Giving information to children helps prevent sexual abuse, Schreck said. The rules seem simple: If someone wants something that seems strange to you, say "no," get away, and tell someone. Also tell someone if you think another child is in danger.

Parents should play the "what if" game with children, Schreck said. Children should be given examples of lies and tricks abusers may use. They should be told never to go anywhere without permission. They should be told that "bad touching" usually involves taking off clothes for no good reason and keeping a secret.

Pediatricians have an opportunity to initiate this type of conversation during the routine medical exam, which is a "good reason" to take off one's clothes. They might also encourage children to speak up if something they do during the exam causes discomfort, Schreck said.

She added it's important for children to be taught the proper names for body parts and, so they are clearly understood when communicating abuse. "Parents and doctors should tell children, 'If you fell I'd see the scrape, but if you're hurt inside you have to tell me, and then I can help.' "

Doctors, she said, can suggest books on the topic of sexual abuse to families (a list is available from the Council), and can suggest extra precautions for homes where both parents work and children take care of themselves.

Sexual abuse varies, Schreck pointed out, ranging from voyeurism or verbal stimulation, to touching, intercourse, or forced prostitution and child pornography. "However, there is little agreement among the public as to what's abusive," she noted, adding that some attitudes can be especially detrimental to boy victims who elicit less sympathy.

HEART IMPLANT, TRANSPLANT PATIENT RIDES HOME WITH SANTA

(Editors, News Directors: Photos of St. Laurent with autographed photo and presenters available on request if not included. The Weibles may be contacted directly at (415) 365-0404. St. Laurent is expected to be available briefly for a photo or interview opportunity at the Stanford University Hospital front entrance on Pasteur Drive at the time of his release, 10 a.m. Saturday, Dec. 8. This is the only interview or photo opportunity we expect with St. Laurent at Stanford.

STANFORD—

Robert St. Laurent, kept alive before a heart transplant on an artificial cardiac pump, was to drive away from the hospital Saturday (Dec. 8) in a limousine with his wife, Santa Claus, and an autographed picture of actress Linda Evans.

"It's a secret," St. Laurent's wife, Cynthia, said Friday morning. "After 113 days in the hospital we wanted to do something special to surprise him."

On Sept. 5 he became the first—and so far only—person ever to receive an innovative cardiac pump, the Pulsemaker Heart Assist System, which kept him alive until a human donor heart was implanted Sept. 13. His stay at Stanford University Hospital was complicated with further surgery for an inflamed colon.

Santa Claus is Wally Weible, St. Laurent's Redwood City apartment manager, who arranged the luxury transport from a friend who runs a limousine service, said Weible's wife, Pat.

"My husband plays Santa every year anyway. We wanted to do this for Bob and Cynthia (St. Laurent) because we are really happy he is able to come home," said Pat Weible.

If all goes as planned, the ride will be the second surprise of a week of recuperation. On Wednesday, St. Laurent's primary nurse, Patti Tharp, and five advanced nursing students presented the recovering patient with the autographed picture of Linda Evans, a star in the television series, "Dynasty."

Dec. 7, 1984

-more-

Julie Shinn, education coordinator for the postgraduate cardiovascular nursing program, said the students contacted officials of the popular television series and explained their patient's interest in the show—and Miss Evans.

"The nurses knew that after surgery the only program I wanted to watch was 'Dynasty,'" St. Laurent said."

The St. Laurents will remain in the area for several months of followup treatment before returning to Florida, Cynthia St. Laurent said.

The couple arrived at the Weible's apartment complex in July when St. Laurent, who suffered from hardening of the arteries, was accepted for the transplant program. For four years he had not been able to work in his job as manager of a recycling plant because of his heart condition. On Aug. 24, his condition had deteriorated substantially, and he was admitted to the hospital.

Doctors feared that without a transplant he was in immediate danger of death, so Dr. Philip E. Oyer, associate professor of cardiovascular surgery, decided with colleagues to implant the experimental Pulsemaker left ventricular assist device (LVAD) as a temporary measure. On Sept. 13, a suitable donor was located, and the device was removed as St. Laurent became Stanford's 313th heart transplant recipient.

The first Pulsemaker implant came about two months after the Food and Drug Administration had approved trials of the device at Stanford. The Pulsemaker offers the hope of becoming a totally implantable, portable heart support system in a few years, Oyer said. He has said it is the first LVAD based on an electronically driven—rather than pneumatically powered—pumping action to be implanted in a human patient.

The FDA has approved a total of 20 implants of the device, and doctors have said it will be used again when suitable patients are identified.

The Pulsemaker LVAD has been developed by Oyer and Peer M.Portner, Ph.D., consulting associate professor of cardiovascular surgery at Stanford. Portner is chief executive officer of the Novacor Medical Corp. of Oakland, which is manufacturing the device.

MEDICAL CENTER WINS ENERGY CONSERVATION AWARD

STANFORD—

Stanford University Medical Center has won the 1984 Energy Management Award for a nonprofit institution from the 300-member San Francisco Bay Area Chapter of the Association of Energy Engineers (AEE).

"We are in the business of trying to reduce the cost of health care," said Sean Mooney, manager of utility services, who accepted the award on behalf of the medical center at the AEE's award banquet in El Cerrito, Wednesday, Dec. 5.

Stanford was selected from among a field of 20 entries, including Pan American World Airways, which won the top prize for energy conservation in the private sector.

Mooney said that energy consumption at the medical center declined 11.7 percent between the start of the conservation program in September 1980 and August 1984.

The decline occurred despite an increase in square footage of 5.8 per cent, Mooney explained.

The reductions resulted in an avoided cost of more than $1 million since the program began, Mooney said.

Many of the changes were technical, Mooney explained, including the relocation of thermostats to provide more accurate responses to avoid overheating work areas. Some changes, he said were relatively simple, such as always cleaning light fixtures every time a bulb is changed to ensure that a maximum of light is utilized.

"And a significant part of the effort involves things as simple as remembering to turn off the lights when you leave work," Mooney said.

Mooney noted that utility costs, which average about $9,000 per day, are higher for medical centers than for most business because of the high concentration of sophisticated equipment required for patient care.

Ann M. Anderson, San Francsico AEE chapter president, and Mooney both noted that Stanford actively sought and received energy research grants and utility company rebates to further minimize utilities expenses.

The AEE is a nonprofit, scientific and educational organization with more than 5,000 members in 21 countries, including architects, engineers, consultants and buildings managers.

DELAYED TREATMENT OKAY FOR SOME TYPES OF CANCERS, RESEARCHERS REPORT

STANFORD—

Delaying treatment for certain types of cancer patients does not compromise their chances for survival, reported Stanford University Medical Center scientists in Thursday's (Dec. 6) issue of *The New England Journal of Medicine*.

However, cautioned Drs. Sandra Horning and Saul Rosenberg, the decision not to treat this select group of patients requires careful, frequent evaluation and sound clinical judgement to begin treatment at the appropriate time.

Horning, assistant oncology professor and Rosenberg, oncology professor and division chairman, studied 83 patients with low-grade non-Hodgkin's lymphomas. These types of cancers are characterized by relatively long survival periods. They found that after five years 82 percent of the patients were alive, and after 10 years 73 percent were alive. They also found that 23 percent of the patients experienced spontaneous regressions, a decrease of the disease. And, progression to higher-risk cancers seemed not to be affected by whether or not the patients underwent treatment.

"We have found that it is acceptable to wait and watch these select lymphoma patients and treat them when it's indicated rather than when the cancer is diagnosed," Horning said in an interview.

Withholding treatment, the scientists reported, has several advantages. Patients can avoid the unpleasant side effects of some cancer therapies. It also allows for spontaneous regression of the disease. And, some treatments have been known to actually contribute to the increasing severity of these types of cancers.

However, Horning said, she hopes these findings do not discourage patients and physicians to continue to work towards improving treatments in these lymphomas.

Today's report follows a similar, controversial one published in 1979, in which scientists first reported that treatment could be delayed based on a study of 44 patients. The current study expanded on the earlier one and shed more light on the natural history of select patients with non-Hodgkins lymphomas, Horning said.

The types of cancers that lend themselves to delayed treatment are called lymphocytic; follicular, small cleaved-cell; and follicular, mixed small cleaved-cell and large cell. There are no known cures to these cancers, the scientists reported, and "early intensive therapies have not increased survival."

The patients began receiving treatment at a median average of three years following diagnosis. Treatment should be started, Horning said, when symptoms begin to show or interfere with other organ functions.

The study was funded in part by grants from the National Institutes of Health.

THE OTHER SIDE OF A FORTY-NINER LINEBACKER

STANFORD—

While most NFL football players look to the end of the season as the time of the year during which they can relax, San Francisco 49er Milt McColl knows it signals the start of long hours of hard work. The defensive linebacker spends the off-season studying at Stanford University School of Medicine, where he's laying the groundwork for a career in surgery.

"He's got his strategy all worked out," says his medical school advisor, Dr. Stephen Shochat. "He's an extremely bright guy."

"He's a great ball player, and he'll be a great doctor," agrees his coach, Norb Hecker.

McColl, who primarily plays on special teams for the 49ers, has been switching between football and medical school since 1981. He finished his medical classroom work last spring and overcame another obstacle during the summer by passing the National Boards—required for all medical students. This January he's a starter on medicine's field—the hospital wards. During his clinical rotations he'll come face-to-face with patients for the first time, considered by many to be the true beginning of a doctor's training.

Until then however, the 6-6, 230 pound "Doc," as he's called by his teammates, is focusing on football. With a 13-1 season to date, the 49ers have a slot in the playoffs and more likely than not in January's Super Bowl. Coincidentally, the game is scheduled to take place at Stanford Stadium.

"I make it a point to concentrate on what I'm doing," McColl says. "During football I concentrate on the game. When I'm in school I concentrate on medicine."

Going back and forth between the two may seem jarring, but McColl "welcomes the change. I've been able to pretty much avoid the burnout many medical students experience because I change what I'm doing every six months."

But being able to take on both careers successfully requires careful planning and, Shochat feels, a special type of person. "Here's a guy who has played football in the Super Bowl, and is going to one of the top medical schools in the country," he says. "He could be prancing around and acting like a prima donna, as if he deserved special treatment. But he's able to put it in perspective and is not terribly impressed with either activity. Milt is a solid, together guy."

"When I'm playing football," says McColl in his soft-spoken, thoughtful manner, "I feel I'm with the elite among athletes in the country. When I'm at school, I feel I'm with the best medical minds in the country. I'm proud, and lucky, to be associated with them."

12-3-84

-more-

McColl was attending his first week of medical school classes at University of California, Los Angeles, four years ago when he found out he'd be playing 49er football. A free agent, he had trained with the team during the summer but didn't have much hope of any season play.

"I was really suprised to hear from the 49ers," he recalls. UCLA didn't want him to divide his time between school and football, so he packed up and moved to Stanford, which had accepted him as well.

"Stanford is the only place I could be doing this," McColl says. "Because of the research orientation of the school, the curriculum is flexible enough to allow me to take half of each year off for football and still get all the necessary coursework done. Stanford encourages students to do other things such as research while they're in school. Football is my research."

The 49ers were in the Super Bowl McColl's first year, so he didn't actually start medical school until late January. "I was a bit worried about coming a month late," he recalls. "My classmates had been following the team though, and they had a little party for me when I came back to school."

Despite such perks, McColl comes back each year prepared for hard work. "Medical school is a serious commitment. You have to really want it," he tells rookie tight end John Frank, a teammate also considering medical school. "Just like football, medical school is rigorous, intense and mentally draining."

But, he says, each profession helps prepare him for the other. "Football teaches you to think and react fast; in medicine you need to be able to make quick decisions. In football you learn how to work with people and cooperate, how to be part of a team effort. Medicine teaches you about your body, how training and diet help you develop it into a finely tuned machine. It also gives me a greater appreciation for what I should do, and should not do but do anyway," he adds with a chuckle.

The strongest tie between the two, McColl points out, is stress. "Football is really a stressful game, and medicine is stressful too. I'm learning how to work well under the pressures of each."

Both football and medical school have another similarity, McColl says. They take time away from his personal life and wife of nearly two years, Cindy, a civil engineer. "We never get to see each other as much as we would like, but I made the decision long ago that family comes first. If there's ever a choice between football, medical school and Cindy, my wife wins out every time," he says. "But that doesn't mean they can't work side by side."

McColl says he has always wanted to be a doctor. He follows in the footsteps of his father, an orthopedic surgeon who played for the Chicago Bears while he was in medical school. The contact with people, and the fact that his father liked his work was appealing, McColl explains.

"It's really important to realize that football is short-term—the average football career is only about four years long. I 'm glad I'll have something to do when I'm done," he says. "A lot of players don't have a goal for after football. That's why some tend to hang on to the game. Sometimes they hang on too long for their own good."

It'll take another three years for McColl to complete his medical education—two or three years longer than it takes most medical students. But, he says, that's fine. "I've got my whole life to be a doctor, and only a short amount of time to play football.

CARDIAC TRANSPLANT CONFERENCE SCHEDULED FOR HEALTH CARE PROVIDERS

STANFORD—

(City and assignment editors and medical/science writers: You are invited to attend a news briefing in conjunction with a three-day conference on "Cardiac Transplantation at Stanford. The briefing scheduled at 12:30 p.m., Wednesday, Feb. 6, in the Cypress Ballroom, Holiday Inn of Palo Alto, 625 El Camino Real, has been organized by the Stanford Medical Center News Bureau for reporters. Individual interviews may be arranged at that time. Technical sessions are limited to preregistered participants from institutions which are considering setting up a cardiac transplant program. Expected to attend the news conference are Dr. John Schroeder, associate professor of medicine and chairman of the screening process for prospective heart transplant patients; Dr. Edward Stinson, professor of cardiovascular surgery and director of the heart transplantation program at Stanford; Dr. Sharon Hunt, clinical assistant professor of medicine and a physician specialist cardiologist in charge of Stanford cardiac transplant patients' followup care; and Mary Lough, a registered nurse who reported a study on life satisfaction reported by heart transplant patients. Also tentatively scheduled to attend are Dr. Norman Shumway, chairman of the department of cardiovascular surgery, as well as heart transplant recipients.

More than 17 years after its first human heart transplant operation, Stanford University Medical Center is offering formal coaching and advice to other medical centers planning similar programs.

A three-day "Cardiac Transplantation at Stanford" conference scheduled Feb. 6-8 has attracted registration from 250 physicians, nurses, social workers and other medical personnel from 38 states and six foreign countries, said Dr. John Schroeder, associate professor of medicine (cardiology), and an organizer of the conference.

He said in a recent interview that a variety of increased scientific knowledge and management skills has enabled research institutions such as Stanford to assist other centers set up programs which will make cardiac transplantation available to a wider public.

Jan. 31, 1985 -more-

"In our own program we have started within the past year to accept both younger and older patients who in the past would not have been considered. A combination of improved medications—including the understanding of proper dosage and maintenance—along with an increased understanding of the social and medical needs of our patients has allowed us, on a case-by-case basis, to accept children as young as 2 1/2 and adults as old as 55."

Between 1970 and 1983, Stanford had limited transplants to persons under the age of 50. No patient younger than 12 had been accepted, although since last September, a 9-year-old and a 2 1/2-year-old patient were accepted and are reported doing well, Schroeder said.

Schroeder credited the modestly expanded criteria to improved drug programs which help prevent the body from rejecting the donor organ while simultaneously allowing the body to fight off infection. A common side effect of the drugs needed to stem rejection is that they compromise the immune system, "but with improved medications such as cyclosporine and with increasing knowledge about dosage, we are able to provide a higher quality of life for our patients."

For younger patients increasing survival statistics have made the operation more feasible and more justifiable socially, Schroeder said. The decision to transplant pediatric patients was made last year after documentation from Stanford and other centers disclosed that the transplanted heart would grow along with patients, said Dr. Norman Shumway, chairman of the department of cardiovascular surgery.

Stanford has done more than 325 heart transplants since Shumway performed the nation's first adult heart transplant procedure on Jan. 6, 1968, less than one month after the first human heart transplant was performed in Cape Town, South Africa. At the time of Stanford's first transplant, patients had a 20 percent life expectancy of a year. Currently, more than 80 percent of the most recent patients are alive a year after transplant and 67 percent are alive after three years, according to the program's statistics. In addition 14 of 20 recipients of combined heart and lung transplantations are alive since Stanford began that dual procedure in March 1981.

Shumway has attributed the increasing survival statistics to the continuous laboratory research program which began with his own experiments—many involving laboratory animals—in the 1950s.

"We constantly receive inquiries from around the world about how a new program may be set up. We regularly have visitors here asking about our program in hopes that some of our experiences may be translated into programs they wish to start," Schroeder said.

"We thought it would be good to try and bring many of these people here at one time for a concentrated conference on the nuts and bolts of running a transplant program," he added.

Schroeder said the number of new programs contemplated or started has increased dramatically within the past two years, and in 1984 an estimated 340 heart transplants were performed worldwide. About 100 hospitals worldwide performed the procedure in the late 1960s but then abruptly halted their programs after experiencing disappointing survival rates.

-more-

But by the early 1970s Stanford, which had based its program on decades of research, stood virtually alone. Since the late 1970s, about a dozen programs nationwide have been active, and in recent years, the number of insitutions regularly performing the procedure has increased to about 25, Schroeder said.

He credited the recent upsurge to both pharmacologic advances, including cyclosporine, as well as an increased willingness by insurance companies and public providers to pay for heart transplants as a therapeutic—rather than experimental—procedure.

In February 1984, Blue Shield of California said it would pay for heart and heart/lung transplants at Stanford, representing the first time a major insurance carrier had stated as a matter of policy it would pay for the procedure. Since then, other insurance companies have offered transplantation as a part of their coverage, encouraging new centers around the country to make the procedure available.

Schroeder said the most significant barrier to transplantation is a lack of sufficient donors.

"If more people were aware of the need for donors and made their intentions known before the potential for donorship arose, we would be able to increase dramatically the number of persons who each year could be transplanted," Schroeder said.

Marguerite Brown, Stanford's donor coordinator, estimated that about 20,000 persons die each year under circumstances which would allow for organ donation of all types, but of that number, only about 2,300 organ donors have actually been available in recent years. Brown said a recent study estimated that at least 1,000 viable candidates each year require a transplanted heart.

The three-day conference is sponsored by Stanford's division of cardiology and departments of cardiovascular surgery and nursing. The course is intended to help physicians, nurses, social workers and other medical personnel understand the needs of a new transplantation program, Schroeder said.

Topics include techniques of evaluating potential recipients from both a medical and psychosocial perspective, physiology, rehabilitation, biopsy techniques and potential risks from immunosuppressive drugs.

Instructors include Stanford physicians, nurses and social workers involved in the Stanford program. Guest faculty include Dr. David Winter, medical director of Sandoz Inc., East Hanover, N.J., manufacturer of cyclosporine.

MEDICAL AFFAIRS VICE PRESIDENT TO STEP DOWN DEC. 1985

STANFORD—

Dr. Lawrence G. Crowley, vice president for medical affairs at Stanford University Medical Center, will relinquish his administrative responsibilities at the end of the year to return to other academic duties, he announced Wednesday, Jan. 30.

In a letter to Stanford University President Donald Kennedy, the 65-year-old vice president said, "I request to be relieved of my administrative appointment effective December 31, 1985. The request, I believe, reflects our understanding of some duration, about my tenure in this office.

"I will continue to provide active leadership of the medical center for the remaining months and I will work closely with you in assuring a smooth transition to new leadership and possible organizational change."

Kennedy said he accepts Crowley's request "with a sense of real regret."

He praised Crowley for his "extraordinary capacity for leadership, exceptional administrative and financial skills, and wisdom and patience to develop consensus even about the most trying issues.

"During the seven years in which you will have served in this role," Kennedy wrote,"you have given unstintingly of yourself in the highest interest of the university and the medical center.

"The improvement of the financial position of all elements of the center, our present opportunity to undertake major facilities renewal in the basic sciences and in the hospital, and the new Children's Hospital venture are all vital accomplishments for which we must thank your foresight and your determination."

Crowley also will relinquish his post of president of the Stanford University Hospital, a university-owned subsidiary.

Kennedy said Crowley will continue to participate in important projects he has begun. These include medical center efforts to raise $145 million for capital projects and endowment, the further planning and development of the New Children's Hospital and the study of the future and organization of the medical center to be supported by the Henry J. Kaiser Family Foundation.

Kennedy announced the appointment of a special committee, headed by Vice President and Provost James Rosse to study Stanford Medical Center's administrative structure.

Whether the deanship of the medical school and the vice presidency should remain separated or be combined in a single person in the future is one of the principal questions the committee will examine.

Crowley joined the Stanford faculty in 1964. He became dean of the University of Wisconsin in Madison in 1973, but he returned to Stanford in 1977. He headed the medical center on an acting basis from 1979 until 1980 when he was appointed vice president, with both the dean and hospital director reporting to him.

"The special needs of (Stanford) Hospital and the significantly increased role of the Hospital Board of Directors," Kennedy said, "require that the (hospital) director function as chief executive officer...with a clear reporting line to the board."

Kennedy expressed hope the committee would make recommendations on the appropriate administrative structure to him by the end of February.

"Resolution of this organizational question is fundamental to the design of a search and appointment strategy suitable for our situation that will win widespread support," he said.

Besides Rosse, the committee includes Dean David Korn of the School of Medicine; Hospital Executive Vice President and Director Sheldon S. King; Hospital Board member Dean Morton; University Board of Trustees member James F. Gaither; Vice President for Business and Finance William F. Massy; Vice President and General Counsel John J. Schwartz; and Professors Thomas A. Gonda, psychiatry; Frances Conley, surgery; and Stanley Falkow, medical microbiology.

FOR IMMEDIATE RELEASE

STANFORD RESEARCHERS REPORT POTENTIAL VACCINE AGAINST GONORRHEA

STANFORD—

Stanford University Medical School researchers have developed a potential vaccine against gonorrhea, a contagious venereal disease that is estimated to afflict more than one million people annually in the United States.

The vaccine candidate consists of a bioengineered protein fragment that appears to produce a protective immune barrier against a broad range of gonorrhea-causing bacteria.

The potential vaccine has successfully blocked gonococcal bacteria from infecting human cells in laboratory studies. It will begin to be tested in human volunteers for safety and effectiveness within the coming year, the scientists said.

The research was led by Dr. Gary Schoolnik, assistant professor of medicine and medical microbiology at Stanford University School of Medicine. Schoolnik's colleagues are Dr. Jonathan Rothbard, research associate; Dr. Rosemary Fernandez, research assistant; Lena Wang, Stanford senior; and Dr. Nelson Teng, assistant professor of gynecology and obstetrics.

Their report will appear in the February issue of the *Proceedings of the National Academy of Sciences*.

In the United States, gonorrhea is the most common communicable disease for which records are kept and in some parts of the Third World, the disease is epidemic. Although usually not fatal, it is a major public health problem because the disease is easily spread through sexual contact and can produce severe complications, including infertility in women, Schoolnik said.

The disease can be treated with antibiotics. However, in some parts of the world, strains of the gonococcal bacterium have become resistant to most drugs.

In addition, people often delay seeking medical help because they don't know they are sick (70 percent of women are initially asymptomatic), because of social stigma, or due to lack of education or access to medical care, Schoolnik said. The result is rapid and unchecked passage of the disease among sexual partners.

To help curb its spread, researchers have long sought a vaccine that could protect against gonorrhea, Schoolnik explained. What has made vaccine development so difficult is that the microorganism that causes gonorrhea has ingenious methods for eluding the body's immune weapons, he said. Schoolnik and his colleagues think they have now made a vaccine that can overcome this problem.

It appears to work by preventing gonococcal bacteria from using pili—specialized tiny hair-like appendages—to latch onto cells lining the urogenital tract. The pili, made of a protein called pilin, enable the bacteria to adhere to cells, the first step in infection.

-more-

The potential vaccine stimulates the immune system to seek out and inactivate the pili, thus preventing the bacteria from adhering.

Past attempts at making vaccines have failed because gonococcal bacteria can continually change the configuration of the pilin protein, thereby always winning a hide-and-seek game with the immune system. The key to the new vaccine's preliminary success is that it stimulates immunity to a portion of the pilin protein whose configuration remains constant and unvaried, even in different gonococcal strains, Schoolnik said.

The researchers made the vaccine candidate by synthesizing pieces of the pilin protein and looking for pieces that didn't vary from one bacterial strain to another.

In laboratory testing, these bioengineered protein fragments were injected into rabbits whose immune systems reacted by making antibody. Blood serum containing the antibodies was taken from the rabbits.

The sera were then tested to find the one that most effectively blocked a variety of gonococcal bacteria from latching onto human cells in tissue culture.

Because animals are not subject to gonorrhea or similar diseases, the next step following laboratory studies is to test the vaccine candidate in humans, Schoolnik said.

First, it will be administered to healthy volunteers to establish its safety, Schoolnik said. The next stage would be a clinical trial in volunteers who are vaccinated and then exposed to gonococcal bacteria, he said.

The new finding is complementary to another potential component of a gonorrhea vaccine developed by Dr. Stanley Falkow, professor and chairman in the department of medical microbiology at Stanford, Schoolnik said.

Falkow and his colleagues have cloned a gene that codes for a protein the microorganisms use to defend themselves from the body's immune system during infection. The cloned gene may help researchers find a way to inactivate this gonococcal defense protein.

One reason a gonorrhea vaccine would be so valuable is because of the disease's side effects, which are most severe in women, Schoolnik said. The major complication of gonorrhea is pelvic inflammatory disease (PID), which can cause chronic pain, ectopic pregnancy (the embryo starts to develop in the fallopian tube rather than in the uterus), and infertility.

With each episode of PID, a woman's chance of becoming infertile rises, explained Schoolnik, beginning at a 17 percent likelihood of infertility after one episode and increasing to a 69 percent chance after three bouts of PID.

"There is an epidemic of infertility caused by gonorrhea in Southeast Asia and Western Africa," Schoolnik said. "In affected parts of Africa, one-quarter of the women are infertile by age 25," he added.

Other complications of gonorrhea include meningitis and arthritis. Children born to mothers with gonorrhea also risk developing serious eye infections, Schoolnik said.

Stanford University is applying for a patent on the protein fragment that forms the basis for the vaccine, Schoolnik said. If the patent is approved, the university plans to grant a license to a French biologicals company, the Institut Merieux in Lyons, which has funded Schoolnik's work on the vaccine's development.

NEW EXPERIMENTAL TREATMENT FOR A COMMON SEXUALLY TRANSMITTED DISEASE

STANFORD—

Stanford University Medical Center researchers are testing an experimental treatment for a sexually transmitted disease that may be associated with one type of cancer and is thought to afflict more than one million people in the United States.

The researchers want to find out if the condition, known as venereal warts, can be effectively controlled with interferon, a powerful virus-fighting protein made by the body.

If successful, the researchers believe that the new treatment, which is in the form of an ointment, could be more effective and less painful than current therapies for the disease.

The venereal wart condition, also called condylomata acuminata, is rapidly becoming one of the most common sexually transmitted diseases in the U.S., said Dr. Nelson Teng, who is heading the research program with interferon expert Dr. Thomas Merigan.

Teng is an assistant professor of gynecology and obstetrics and Merigan is professor of medicine and head of infectious diseases at Stanford University School of Medicine.

The disease, caused by the human papilloma virus, consists of wart-like lesions in the genital and anal regions of both men and women. It is easily spread, difficult to cure, and the human papilloma virus has been associated with cervical cancer, Teng said.

The disease is of growing concern because it has become "nearly epidemic in some populations, such as among gay men and also among heterosexuals in some areas, particularly some small college towns," said Barbara Story, a physician assistant and researcher on the project.

"Interferon looks very promising as a potential treatment for venereal warts because it enhances the body's own defense system against viruses and malignant cells," Story said.

Traditional treatments for the warts—chemicals, burning, freezing, or surgical removal—are painful and frequently ineffective, Story explained.

But recent positive results from studies overseas using interferon injections to treat venereal warts have encouraged the Stanford scientists to test applications of the protein in a gel form, Teng said.

A special chemical in the gel will carry the interferon through the skin to reach the sites of viral infection, Story said. A gel will be tested rather than injections because its painlessness and convenience should increase patients' compliance and eliminate side effects, she added.

The researchers will conduct initial studies of the gel on 90 women with venereal warts, Story said. Volunteers must be 18 or older, have had no treatment for the warts within the past four weeks, and must not be pregnant or nursing.

The study will last six months. Participants will be required to apply the gel three times a day for four weeks, make weekly visits to Stanford for the first month, and less frequent visits thereafter.

"We anticipate no adverse side effects from the treatment," Teng said.

To inquire about the study, women should call Stanford's department of gynecology and obstetrics at (415) 497-8585.

KIDNAPPED FOR SPEAKING OUT AGAINST HIS COUNTRY'S HEALTH CARE POLICIES—ONE EL SALVADOREAN PHYSICIAN'S STORY

STANFORD—

Dr. Rafael Ruiz Izaguirre is fighting in El Salvador.

Not with guns and bombs hiding out in the hills, but with words and facts, he said, in newspapers, from podiums, anywhere he can speak out against the government's health care system.

His battle has ostracized him from some social and political circles, he claimed. It has kept him out of professional positions to which he might have been appointed.

He was once kidnapped and interrogated for his outspoken and controversial views. But that hasn't stopped him.

Ruiz is fighting to save the lives of the children of El Salvador, he said.

A neonatology fellow at Stanford University Medical Center from 1969-70, Ruiz, currently head professor of the neonatology division at the National University of El Salvador's School of Medicine, has returned to the United States for the first time as a Fulbright professor at Stanford.

His visit also marks the first time he's been willing to discuss not only his activities in El Salvador, but his kidnapping nearly four years ago by "a heavily armed squad" posing as leftist rebels.

Fighting for better medical care in his country isn't easy, Ruiz said in a recent interview. As he tells it, he was walking through his clinic parking lot towards his car on July 16, 1981. Suddenly, he was surrounded by four strange men. One held a rifle to his forehead.

Ruiz was searched, blindfolded, handcuffed and stuffed into a small van. He was not mistreated, he said, but nobody spoke during the drive that brought him to a cold, bare room in a building at an unknown destination. About two hours after his arrival, a man walked into the room.

After many personal questions, to all of which the interrogator already knew the answers, the key question, Ruiz felt, was asked. "You are a prisoner of the Farabundo Marti National Liberation Front (FMLN). Why have you betrayed us?"

"You are wrong, I do not belong to FMLN," Ruiz said. "I have not betrayed you or any other political group. I do not belong to any.

"My work is not political, it is medical," he continued, spilling out his frustration and anger towards "the ineptitude and the arrogance" that he had seen so frequently in members of El Salvador's health ministry.

"No matter who is in the government," the interrogator finally asked, "will you insist in protesting when you consider that things are not done correctly?"

"Yes," Ruiz replied.

Ruiz was again blindfolded and driven to within walking distance of his home. He had survived.

The kidnappers were not guerrillas, Ruiz is convinced, because of small but revealing mistakes they made that the FMLN, or any rebel group, would not have made. Also, the respect with which they treated him made him think they appreciated his work. Nonetheless, they were trying to find out if he was a member of the leftist group, and if so, to intimidate him. He was never treated roughly or with any violence, he pointed out, and the interrogator was at no time disrespectful.

He was intimidated—outright paranoid, he admitted—for a few weeks following his ordeal, but gradually returned to his outspoken criticism of the government.

Public health care in El Salvador is abysmal at best, Ruiz said. Those wealthier citizens who can afford to pay for private physicians *can* get good medical care. But for 75 percent of the country's population that makes up the lower and poverty classes, many diseases that are easily preventable can lead to a major disability or death.

The major health problems among children in El Salvador, Ruiz said, include malnutrition, affecting an estimated 75 percent of those children who fall into the lower end of the socioeconomic scale; gastrointestinal problems, many of which result from parasitic infestation caused by bad environmental hygiene; communicable diseases, the result of lack of immunization; and others due to mere negligence by health authorities, he charged.

"I'm not advocating anything unusual," he said. "I'm talking about the ABC's of medicine. It's not my idea to vaccinate against polio, to provide proper nutrition—it's all written in medical literature.

"Many doctors working as government officials in El Salvador suffer from 'incurable O.K.ism'. They refuse to see or hear anything. Malnutrition, for example, is not just a medical problem, it's a social problem as well. If they accepted the responsibilty for poor people's care, they'd have to make drastic changes. It's much easier to ignore the problems."

So, Ruiz continued, the attitude becomes one of denial. "They sayth'We don't have polio. Why make changes if there is no problem?' "

It was in medical school during the early 1960s that Ruiz's anger towards the health care system started to build. Helpless to do anything while in school, he vowed to spend his medical career teaching and working to improve public health care. It was that same sense of responsibilty that most other doctors avoided that led him to his decision.

"I got scholarships for my education, and the money for those scholarships came from the people paying taxes," Ruiz said. "I realized from the beginning that there was something deeply wrong that I could not tolerate. When I went back to El Salvador in 1971 after all my training I wanted to do the best for the people who had paid for my education. The people who could pay for medical care didn't need me."

-more-

Ruiz clashed with government officials on many occasions. While he was working at a small country hospital, for example, the head of the anti-malaric division declared there was no malaria in the region. Ruiz countered, saying he saw at least two cases each day.

In another small village, Ruiz was refused permission to study deadly insects invading citizens' adobe huts because of personal grudges, he believed, between those who needed to approve it.

In a maternity hospital in the capital of San Salvador, Ruiz was removed from the premature infant unit after his patients, whom he fed as well as possible, started doing better than those of the unit's head doctor, who fed the preemies tea. He later coined the term 'hospital-dematernititis' to describe the mixture of negligence and apathy that he felt abounded.

He continued his campaign, pointing out wrongdoings to medical students he taught, publishing articles in newpapers—some considered leftist and radical, and some more mainstream. No one would join his protest, Ruiz said, because they feared repercussions to their professional and social status.

"Some may say I am stupid to speak out," Ruiz said. "I've exposed my life, my well-being, my family and the social prestige awarded doctors in El Salvador.

"But I don't feel I have the right to remain silent."

His efforts, he said, seem to be paying off.

He and some associates have founded the Association of Perinatal Medicine. Through this group, Ruiz plans to open a model clinic in San Salvador by August that would employ the services of paramedics and other health care professionals. The goal of the clinic, which is being funded jointly by his university and a group similar to this country's Kiwanis Club, is to offer good medical care at a fraction of the cost of a private doctor.

"We'll be creating a new health team," he said. "This is something I've been proposing since 1977, but the government has been deaf, blind and just not interested."

Ruiz also is encouraged by the choice of the country's new secretary of health, whom he thinks may improve the situation. Maternal and child health care as a governmental policy is finally beginning to take shape, Ruiz said. He, in turn, will start pressing more for family planning, maternal and child health care and preventive medicine.

With professional acquaintances of many American doctors, Ruiz knows it would have been relatively easy to move to the United States and practice medicine here. But, he said, he will never leave El Salvador unless it becomes dangerous for his wife and two sons.

"My country is like my family," he said. "We Salvadoreans are very stubborn people. I'm taking risks by being an open dissenter, but I'm at peace with myself."

FOUNDATION STUDY TO EXAMINE FUTURE DIRECTIONS OF ACADEMIC MEDICAL CENTERS

STANFORD—

A major study of the future of the academic medical center will be conducted in the next three years under the direction of Dr. Lawrence G. Crowley, professor of surgery and vice president for medical affairs at Stanford University Medical Center.

The study, made possible by a $650,000 grant from the Henry J. Kaiser Family Foundation to the university, "will examine how academic medical centers can adapt to a competitive medical practice environment," according to Dr. Alvin R. Tarlov, president of the Menlo Park, California-based foundation.

"Stanford Medical Center," he said, "is now functioning in a competitive environment that may become the norm throughout the country in a few years.

"The choices Stanford makes will be influential in shaping the future organization of academic medicine in the U.S."

Planned as a cooperative effort of the university, the medical school, and the university hospital, the research will be guided by an internal steering committee, augmented by an advisory board representing business leaders, the medical community, the public sector and other academic health centers.

Smaller task groups will be convened to study and make recommendations on specific trends that affect the missions of the medical center in patient care, research and education.

Tarlov said policy makers are presently hampered by a shortage of information from which to propose changes for the future direction of academic medical centers.

"We believe the study will address this issue," he said.

"Academic medical centers play a key role in the American health-care enterprise," explained Crowley. "They educate physicians and other health care professionals.

"The centers generate new technologies and the most advanced medical knowledge. Their staffs operate the major high-technology, high-cost hospitals that provide advanced forms of diagnosis and medical treatment.

1-25-85

-more-

"The complex social role of academic medical centers brings them into a daily contact with the public, the body politic and the federal government which provides a major portion of their funding.

"The increasing competition in the health care market has created enormous stresses on the academic medical centers. These must be dealt with effectively if their missions of academic medicine are to be preserved."

The study will go beyond the traditional questions of excellence and quality, Crowley said.

Among the questions are which activities, for example, are essential to the center's mission? How should it be organized to manage risks and be cost-competitive in terms of attracting patients? How should it be governed? How should patient care relate to education and research? How compatible are academic policies and university governance with the service obligations of the faculty physician, the center, and the community? And who should pay for the costs of medical education?

"There is a shift in the types of patients who come to the academic medical center," Crowley said. "The elderly represent a growing proportion of patients who have unique and highly expensive medical needs.

"The center draws a sicker and more complicated mix of patients requiring large, specialized staffs and the most advanced medical technology. Government efforts to cut costs in the face of this puts the academic medical center in a predicament."

Another trend is that more patients formerly treated in hospitals are now seen in outpatient clinics. And new institutional arrangements and hospital-physician joint ventures are emerging.

"The new environment," Crowley said, "has led to an erosion of the revenue base that has traditionally supported the patient care role of academic medical centers. And society has yet to provide alternatives commensurate with their contributions to society."

FOR IMMEDIATE RELEASE

STANFORD SCIENTISTS CRITICIZE PROPOSED CUTS IN N.I.H. FUNDING

STANFORD—

Stanford University scientists are voicing strong criticism of a Reagan administration proposal to reduce federal support for biomedical research this year below the levels authorized by Congress.

"President Reagan is betting on the wrong war," Dr. Paul Berg, a Nobel Prize winner and professor of biochemistry, said Tuesday, Jan. 22.

"He is increasing defense budget spending at the expense of the war on disease. I think the reduction in proposed grant support is outrageous and it will prove extraordinarily costly in the long run."

"It is a very calamitous decision," said Dr. Arthur Kornberg, also a Nobel Prize winning biochemist known for his work on the genetic code.

Kornberg said the cuts would have "profound and harmful" effects for research, with serious consequences for the nation's efforts to improve the diagnosis, treatment and prevention of disease.

"The proposed cuts are drastic," Kornberg said. "They would affect the activities of some 25 percent of the nation's most productive biomedical scientists, young and old, as well as the entire spectrum of research on diseases and basic science.

"The cuts would not only destroy a large segment of our scientific talent, but they would send a message to our younger scientists that they cannot be assured of support even if they have done distinguished work and spent years in specialized training."

The Reagan administration has proposed to reduce the number of competitive grants awarded by the National Institutes this year by 23 percent: from 6,500 to 5,000. The cutbacks will affect the full range of research, including the studies of cancer, heart disease, arthritis, immunology, cell biology, molecular genetics, neurological disorders and stroke.

Administration officials, quoted in news articles, have said the cuts will save $280 million in the current fiscal year and at least that amount in each of the next two years. Congress has appropriated $5.1 billion for the NIH in fiscal 1985.

But medical school administrators throughout the country have criticized the impounding of funds already authorized by Congress as arbitrary.

1/23/85

-more-

Dr. David Korn, dean of the Stanford University School of Medicine, said the decision by the Congress to increase the NIH budget at levels substantially higher than those requested by the administration reflected two important facts:

"One was the current state of progress in biomedical research," Korn said, "and second the recognition that research funding had failed to keep pace with developments coming from some of our best biomedical research institutions," he said.

The 6,500 research grants earmarked for 1985, the dean explained, represented a highly desirable step to redress this serious imbalance.

The decision of the Office of Management and Budget to "manipulate funding already authorized represents a contravention of the will of Congress," Korn said. "It freezes biomedical research and contract support at a level already shown to be grossly inadequate."

"I am particulary concerned about the effect of the cuts on young scientists who will essentially be without funds," said Robert Lehman, profesor of biochemistry.

He said the cuts were coming at the wrong time.

"All these years basic scientists had to defend what appeared to be basic research of seemingly little practical value," Lehman said. "The wisdom of this approach, however, has been shown to be correct."

Lehman said recent discoveries by various researchers concerning oncogenes (cancer genes), the identification of the chemical structure of a virus, which may prove to be the causing agent in Acquired Immunodeficiency Syndrome (AIDS), for example, were accomplished in a short time.

"But that was not by accident," Lehman said. "It was because of two decades of fundamental research that provided the knowledge and tools to isolate the virus, identify it, and learn about its structure. So it makes no sense to reduce support at a time research is paying off."

Dr. Stanley Cohen, chairman and professor of the Department of Genetics, termed the Reagan administration proposal "sad."

"It comes at a time when increasingly major strides have been made in biomedical research and the opportunities to benefit the public by even greater strides now exist," Cohen said.

It's distressing, he said, that the administration has chosen to use what is apparently a legal technicality to thwart the intent of Congress.

Kornberg criticized what he termed "the arbitrary process by which the Reagan administration has dealt with cuts.

"It's detrimental to the kind of flexibility that has insured the success of the NIH," he said.

"And it sets a precedent for future arbitrary action that could seriously damage the uniquely successful American effort in biomedical research."

NEUROLOGIST WARNS EPILEPTICS OF WATER-INDUCED WEIGHT LOSS PLAN

STANFORD—

A diet program which advocates drinking large quantities of water to promote weight loss may trigger seizures in epileptic patients, says a Stanford neurologist.

Dr. James C. White, who serves on the voluntary teaching faculty at Stanford Medical Center, said during a recent five-month period, he observed grand mal seizures in three patients who were following a diet advocating the drinking of eight to 12, 8-ounce glasses of water per day.

White did not identify the weight loss plan.

He said that hydration, or drinking unusually large quantities of water, "is one of the oldest mechanisms known to induce seizures, and patients with seizures have been thought to be especially vulnerable to its effects." He said medical science is unsure why drinking water induces seizures in patients whose epilepsy had been controlled.

White emphasized that non-epileptic patients did not appear at risk of having seizures as a result of drinking moderately large quantitities of water.

One of the patients cited by the neurologist, a 34-year-old woman, had never suffered a major seizure until beginning the large water intake program. Another patient, 33, suffered from genetically determined epilepsy but had no major seizures for three years until the diet. The third patient, 21, had suffered seizures as a child as a result of a fever but had been symptom free for five years until the diet began.

"In view of the widespread use of this diet system and the fact that patients with well-controlled seizures have often resumed such activities as driving an automobile and swimming, physicians should be aware of possible danger to these patients," White wrote in a letter published in the Jan. 24 issue of the ***New England Journal of Medicine***.

"Should other reports of loss of previously attained seizure control in patients on this diet plan be forthcoming, the wisdom of allowing such patients to follow its recommendations (involving water intake) should be questioned," he said. He emphasiuzed in an interview that the observation of three patients "doesn't prove anything, but we do have to ask the question, 'is it advisable to use that much of a fluid intake in patients who have epilepsy?'"

White is in private practice as a neurologist in Los Gatos, Calif., in addition to his voluntary teaching duties as a clinical professor of neurology at Stanford.

NEW MICROSURGERY LAB FOR STANFORD'S PLASTIC AND RECONSTRUCTIVE SURGERY

STANFORD—

Stanford's plastic and reconstructive surgery division has been able to update and expand its microsurgery laboratory thanks to the generosity of a former patient, said division head Dr. Lars Vistnes.

The new lab, equipped with about $75,000 raised through the efforts of Beverley Hills resident Bernice Gershon, was dedicated during a small ceremony Jan. 17.

"We now have the most modern microsurgery laboratory available," Vistnes said.

The advent of microsurgery—techniques with which surgeons can cut and splice vessels, nerves, muscle, tendons and more with minuscule tools they maneuver while peering through a microscope—is considered one of the most dramatic in years, Vistnes said. It has allowed surgeons to transfer parts of the body—a toe to the hand, for example—and to reattach severed parts that in the past would have been lost.

The funding enabled the division to purchase a new operating microscope that allows two surgeons to participate in the operation. An attached video camera records the procedure and a viewing screen allows others to observe without interfering. The procedures can be played back at other times for critiquing as well as for teaching purposes.

Stanford's division includes seven fulltime faculty members and 18 residents training to be plastic and reconstructive surgeons in the six-year-long program.

With the funds the division also purchased sets of microsurgery tools—forceps, scissors and clamps with tips thinner than one strand of human hair—to lend to physicians-in-training and to use in the lab.

Gershon was referred to Vistnes about two years ago for reconstructive surgery following a bout with cancer. Upon her recovery, Vistnes said, she told him she'd like to help him financially. He suggested the need for updated equipment for his lab.

"She's a human dynamo," Vistnes said of Gershon. She formed a non-profit organization, Friends of Reconstructive Surgery Research, and sponsored a series of fund-raising events. Her organization teamed up with the Eddie Cantor Charitable Foundation, and the proceeds—about $50,000—from their 1984 annual benefit dinner also went to Vistnes' lab.

BERGER HOLDS FIRST NORRIS PROFESSORSHIP

Editors: Photo of Berger available on request.

STANFORD—

The Kenneth T. and Eileen L. Norris Foundation of Long Beach, Calif., has pledged $3 million to Stanford University for a research endowment, facilities improvement, and endowed professorship for the director of the Stanford Mental Health Clinical Research Center.

Dr. Philip Berger was appointed the first Kenneth T. Norris, Jr. Professor of Psychiatry and Behavioral Sciences at the school of medicine, by the university board of trustees at its Dec. 11 meeting.

Berger, a professor of psychiatry, is noted for his work in the field of psychobiology, the study of interactions between mind and body. He has identified contributing biological causes to mental illnesses such as schizophrenia and depression, and pharmacological treatments for such disorders.

He received a B.A. in 1965 from Dartmouth College and his M.D. from Harvard Medical School in 1969. He has published extensively in journals and textbooks, while distinguishing himself as a researcher, teacher and clinician.

Berger has served as director of the Stanford Mental Health Clinical Research Center at the Palo Alto Veterans Administration Medical Center since the NIMH-funded center was established in 1977. Used by researchers worldwide to test biological aspects of psychiatric disorders, the center provides a setting in which advances in basic sciences may be applied to improve the evaluation and treatment of severe mental disorders.

The Norris Foundation was founded by the late Kenneth T. Norris and his wife Eileen L. Norris, of the Los Angeles area, in September 1963. Kenneth T. Norris, Jr. was a founder and is currently chairman of the five-member board of trustees. He succeeded his father as chairman of the board of Norris Industries, a manufacturing conglomerate, and then he retired to devote more time to philanthropic, cultural and civic activities.

The Norris Foundation provides support for a wide variety of philanthropic activities, but its principal thrust is in the area of medical education and research.

SPANISH INTERPRETERS: BUILDING A PROFESSIONAL NETWORK

Photos available on request if not included.

STANFORD—

Of all the people hovering about, dispensing medications, taking lab tests and performing surgery, Josefina Fayard brings light in the tunnel to a confused Spanish-speaking patient at Stanford University Hospital.

Fayard is one of four Spanish interpreter/translators on staff at the hospital, and as such serves to bridge the linguistic gap between Stanford doctors and health professionals, and the majority of their non-English speaking patients—some of whom become very attached to the one person they can speak with.

"The service we provide is important," said Eva Wasmer, "because in a medical setting both technical terminology and cultural attitudes must be clearly understood by both sides." Three interpreters on duty at any one time each receive a minimum of 10 requests per day, and usually more.

What adds to both the challenge and rewards of their job, say the four, is that they not only learn about new medical procedures daily, but get to work closely with people from all socioeconomic backgrounds.

Although hospitals, under mandates of federal legislation, are required to protect the rights of non-English speaking people by providing interpretation and translation services, the four from Stanford found that very few hospitals have formal programs in place. Most, they say, use bilingual employees or volunteers who have no medical background, to fill in as needed.

To ensure that those providing language services are properly qualified for the job, whether salaried or not, they started in December 1983 a project which they hope will offer a model for other hospitals to follow. This project, the American Medical Language Services Network, currently has about 70 members representing 40 or more health agencies, hospitals and community organizations.

The network, the four say, will be instrumental in developing a certification process to ascertain the language proficiency of those being used as interpreter/translators. It will institute a Medical Interpreter/Translator Code of Ethics, develop materials for the training of hospital volunteer interpreter/translators, and educate the public in general as to the functions of the medical interpreter/translator.

"Interpretation in a medical setting is not always literal. It is very different from court interpretation, which is simultaneous and verbatim," Fayard said. "The hospital setting encourages us to sensitize the health professional to the patient's background and cultural perspective, which can affect the way something is said or understood."

-more-

One of their main objectives this past year has been to discourage the practice of using non-English speaking family members—in particular children—as conveyers of medical information. Often the relative fails to inform the patient of impending treatments or bad news for fear of upsetting the patient, they said.

Some physicians and health professionals make the mistake, John Chavez said, of assuming that patients who understand a bit of English will completely understand instructions. Possible problems can be avoided if an interpreter/translator is called upon to clearly explain the diagnosis, proposed treatment, or medication instructions.

Maternity patients present special challenges. Often, because of heightened embarassment characteristic throughout the Hispanic world, the wife does not want her husband present at a birth, Fayard said. "Doctors may not understand how these women, many of whom already have several children, can be so embarassed even during a pelvic exam." Sometimes the husbands themselves feel out of place, and also object to others (like medical students) watching the delivery.

The issue of terminal illness is especially tricky also, said Pyka. Some Hispanic families insist on withholding the truth from the patient when it comes to impending death. The interpreter can explain the family's wishes to the doctor, who may or may not then insist that it is the patient's right to know. Although the interpreters always comply with the physician's decision, their role is not without influence, they agreed.

"We four are from different countries and backgrounds," Wasmer said, "and we're always trying to learn from one another."

Fayard is from Mexico, Pyka from Chile, Chavez from El Salvador, and Wasmer of Nicaraguan descent. Pyka is presently in the Ph.D. program in physiology at Stanford, Chavez is a Ph.D. candidate in early childhood education at U.C. Berkeley, and Wasmer has a degree in German. Fayard has many years of experience as an interpreter/translator combined with an education both in the U.S. and Mexico.

The four have begun to work with volunteers in Stanford Hospital's translator bank, which represents many different languages. Volunteers are classified according to both language proficiency and familiarity with medical terminology. "Someone may be perfectly able to interpret 'bladder' but at a loss to interpret 'gall bladder,' " Chavez explained. The level of proficiency determines which volunteers can handle which patient situations.

The four stress that translation (of the written word) is different from interpretation (of the spoken word). "Some people can do one but not the other," Chavez said.

Besides direct medical interpretation, their job includes translating medical histories, data, consent forms and other necessary documents, fielding patients' calls from both near and afar, translating physicians' articles and lectures, training volunteer interpreters, and talking to professional groups.

One fact the four understand well is that both doctors and patients sometimes get impatient when relying on an interpreter/translator. "At a teaching hospital like Stanford," Pyka said, "a lot of people enter the patient's room. Many patients feel lucky to be at such a world renowned hospital, but at the same time they rely on us to help them maintain dignity and to keep them fully informed of what's going on."

Although the four often feel spread a bit thin, there is no extra charge for their services. They are regular hospital employees, reporting to Wilbur Wright, director of the department of clinical social work. Olga Guerra, now a Stanford Hospital social worker, became the hospital's first interpreter/translator 13 years ago and ran the service alone for six years.

HOSPITAL MAKES SUPER BOWL PLANS FOR EMERGENCY ROOM

STANFORD—

Barbara Behrens will be spending most of Super Bowl Sunday at Stanford Stadium, monitoring the emergency medical needs of a mid-size city temporarily plunked down on the mid-peninsula for a day.

Behrens, assistant director of emergency services at Stanford University Hospital (SUH),and Ellen Pilling, Cowell Student Health Center Nurse Practioner, will coordinate five ambulances, three aid stations with the SUH emergency department, which is located about a mile from the stadium.

Unless there is a brief break, most of the emergency medical crews (which include four emergency physicians, four registered Mobile Intensive Care nurses and eight emergency medical technicians) won't get to see the game.

But two crews will get to watch the game as long as they don't have to leave their posts inside the stadium to carry a patient to the hospital emergency department.

Being the nearest full service hospital to a phenomenon such as the Super Bowl is about equivalent to suddenly creating a new city of about 150,000 persons, she said. Besides 85,000 spectators, officials have estimated the Super Bowl will bring tens of thousands of additional persons who want to celebrate the event nearby.

"We will have plenty of help in our effort to provide emergency care," said Behrens. "Three physicians, six registered nurses and six other assistants are being provided by the Cowell (Stanford student) Health Center, and a local company (St. Claire Ambulance) is providing four ambulances with two emergency medical technicians aboard each.

"But unlike a community, a high percentage of these people are away from home and their family doctors. With the large numbers of people, we'll have to anticipate that a certain percentage of them will require medical care and that they will turn to us."

Communications is a particular concern, and a radio network linking medical services with ambulances, the stadium, local law enforcement and public safety agencies has been established for the day. "We've been working closely with all relevant public agencies, including the city of Palo Alto, Santa Clara County and the state," she said.

Public agencies have provided additional police personnel and altered nearby routes to facilitate traffic and help emergency personnel, including physicians enroute to the hospital, reach their destinations.

On site medical care for players is being provided by the teams and the National Football League, "but we have had discussions with the league and teams about the logistics of providing hospital care if needed," Behrens said.

"We are fortunate at Stanford to have tertiary care facilities to respond to the usual and unusual emergencies if needed. At any given time we have a variety of specialists on duty.

ANNIVERSARY PROMPTS NURSES TO RECALL 1ST HEART TRANSPLANT

STANFORD—

It was late on a wintery evening in January of 1968 when nurse Betsy Fowler received the call at home. "Come into work," said the voice on the telephone from her fellow nursing instructor at Stanford University Hospital's intensive care unit (ICU). "The first heart transplant is going on right now. The patient will be here soon."

Seventeen years and more than 320 heart transplants later, the surgical procedure is considered by many to be routine. Yet the nurses who helped care for that first patient remember the experience in detail.

The event for which the ICU nurses had been preparing for months was finally happening. They had long ago picked the room in front of the nurses station in which the patient would stay; housekeepers had spent hours scrubbing every last inch to make it sterile. They were called in for a final cleaning before the patient arrived.

The nurses had decided between themselves that the instructors--Fowler and Donna Pronko--would care for the patient first. The others stayed on past the end of their shifts to watch the historic event. They had followed the progression of Dr. Norman Shumway's heart transplant research, and had felt upstaged when South Africa's Dr. Christiaan Bernard performed the first one just a few weeks before using the techniques Shumway had perfected. But this one, they felt as they waited for the patient to arrive in the ICU, would be different. The third heart transplant in the world--the first adult in the United States--would be a success.

It wasn't a success, but it wasn't a complete failure either, recalled Fowler and Kathy McDonald, who cared for heart recipient 54-year-old Mike Kasperak for two weeks until he died. "His body didn't reject the heart," Fowler said in a recent interview, "rather his heart rejected his body." "Too many of his other organs were too weak to survive," McDonald explained. "But the new heart worked perfectly until the end."

Still working at Stanford, the two nurses have their memories. McDonald's woodgrained scrapbook is filled with yellowed newspaper clippings to recall the event that literally put Stanford hospital and its cardiovascular service on the map. And their participation in caring for Kasperak showed the world just how important key nurses are to patient care.

Kasperak was wheeled into the ICU about 11 that night. Two nurses at a time were assigned around the clock to care only for him. A respiratory therapist and a physician also shared the small room and kept a night-long vigil. "The procedures we had to do for Kasperak were basically the same as for open heart surgery patients, but it was the excitement and responsibility we felt that made it different," Fowler said.

Kasperak went back to surgery to stop internal bleeding that first night, Fowler recalled, "and I went to the john and threw up." There was just too much going on, she explained. "It was an exciting disaster," McDonald agreed.

Not only did the nurses have Kasperak to contend with, but a full unit of very sick patients and a shortage of nurses to work as well, McDonald remembered. "Physicians and other medical people came in throngs to see Kasperak, and we had to keep them out. And then there were all the reporters! One climbed up on the hospital roof and tried to lower himself by rope to the window so he could photograph Kasperak. They were all looking for a new and different angle," she said.

As the days went on, Kasperak's condition worsened. He had a tracheostomy tube inserted in his throat to help him breathe, he went on dialysis after his kidneys failed and he suffered from more internal bleeding. The nurses, many of whom worked 24 hours at a time, grew weary, as did the physicians, who sat in Kasperak's room all night and carried on their normal operating and patient schedules during the day.

One day Dr. Edward Stinson, who heads up the transplant team today, laid down to take a nap, Fowler and McDonald recalled, and "fell into a coma" for more than a day. "We were all just catnapping whenever there was time," Fowler said. "I was in a fog the whole time."

Fourteen days after the historic transplant, Kasperak died of what Shumway then termed "a galaxy of complications." But the groundwork was laid. After 17 years and 326 heart transplants, and 23 heart-lung transplants, the survival rate is forever improving. Today heart transplant patients have an 81 percent possibility of surviving one year, and a 67 percent chance of surviving three years. Surgical techniques and equipment are more advanced; new antirejection medications are more effective. Instead of caring for transplant patients on a general ICU, nurses today guard their charges on a new unit specially designed for the special needs of the patients.

Now working in the comparable calm of the recovery room, Fowler and McDonald admit they would not be able to care for transplant patients today because of all the medical advances and even more, because of the emotional drain of getting involved with the patients. Pronko has also moved on; today she serves as patient relations coordinator. Yet they look back on their experience in helping care for Kasperak as one of the highlights of their careers. Would they have missed a moment of it had they had a choice? "No way," they agreed.

MONOCLONAL ANTIBODY TO BE TESTED IN MULTIPLE SCLEROSIS PATIENTS

STANFORD—

A genetically engineered protein that reverses an experimental form of multiple sclerosis in mice will be tested for the first time as a potential treatment for patients with multiple sclerosis, according to scientists at Stanford University School of Medicine, Columbia University, and Becton Dickinson Monoclonal Center, Inc. in Mountain View.

The protein is a monoclonal antibody, one of the so-called "magic bullets" that can zero in on individual body components and help destroy abnormal cells or invading disease-causing agents.

Clinical tests of the antibody molecule should begin within the coming year in multiple sclerosis patients, said Dr. Larry Steinman, assistant professor of neurology at Stanford University School of Medicine.

Steinman and his colleagues published a report in the January 25 issue of *Science* magazine demonstrating that injections of the antibody were able to halt development of a multiple sclerosis-like disease in mice.

But anticipating that humans might reject the mouse antibody, the scientists may use a new type of genetically engineered monoclonal antibody molecule that is part-mouse and part-human, developed by a team of researchers from Columbia University, Becton Dickinson Monoclonal Center, and Stanford.

The rejection problem has up to now marred tests of monoclonal antibodies in humans, since most of the proteins available for testing in patients are mouse proteins, said Dr. Leonard Herzenberg, professor of genetics at Stanford, and a co-author of the *Science* report.

Because the new mouse-human molecules are mostly human they should be accepted by the patient's body and therefore should be more effective and safer than mouse antibodies, the researchers believe.

Because the new antibodies are partly mouse, scientists can easily produce them in the laboratory by modifying the mouse antibodies that are already available.

The new mouse-human monoclonal antibodies are not limited to multiple sclerosis in their possible uses, Herzenberg said. They could be more effective than the currently available all-mouse antibodies against other ailments such as some cancers and autoimmune diseases, and potentially in bone marrow transplantation, he said.

Co-authors of the multiple sclerosis report are Matthew K. Waldor, a neurology graduate student; Dr. Subramanian Sriram, formerly a neurology research associate and now on the faculty of the University of Vermont; Dr. Richard Hardy, genetics postdoctoral researcher; Dr. Leonore Herzenberg, genetics senior research associate; Mae Lim, neurology research associate; and Dr. Lewis Lanier of Becton Dickinson's Monoclonal Center.

Development of the mouse-human "chimeric" monoclonal antibody was described in an article in the November issue of the *Proceedings of the National Academy of Sciences* by Dr. Vernon T. Oi of Becton Dickinson, Dr. Sherie L. Morrison, professor of microbiology from Columbia University, Herzenberg, and Dr. M. Jacqueline Johnson, former graduate student in Stanford's department of genetics.

Multiple sclerosis (MS), a chronic neurological disease, affects as many as 250,000 people in the United States. It is thought to be an autoimmune condition, a self-destructive attack by the body's defense network against the very tissues it is meant to protect from disease.

In patients with MS, the target of immune attack is an insulating sheath that surrounds nerve cells. Destruction of the sheath leads to neurological damage and MS's characteristic symptoms, which may include weakness, paralysis, tremors, and disturbances of speech and vision.

Multiple sclerosis usually strikes in young adulthood and lasts for the remainder of the person's life, often as long as 20 to 30 years. There is no effective treatment, although many patients go through long periods of spontaneous improvement between bouts of the disease and many can lead relatively normal lives.

In mice, an MS-like disease called experimental allergic encephalitis can be brought on by injecting animals with ground-up nerve tissue. In an overreaction to the injected foreign material, the animals' immune systems begin to attack their own nerve tissues, Steinman explained. Within days, the mice become weak and develop hind limb paralysis, sometimes leading to complete paralysis and death.

The researchers reported that the monoclonal antibody they have developed reacts with certain cells of the immune system to prevent allergic encephalitis.

Symptoms of encephalitis failed to develop in all mice that were given the monoclonal antibody prior to the nerve tissue injections. In contrast, the disease developed in 90 percent of control mice that were not given the experimental antibody.

When the antibody was administered to mice after the injection had induced early signs of encephalitis, the disease's progress was halted in 90 percent of the animals, they said. Marked improvement was obtained even if the antibody was given to mice in the paralytic stages of the disease.

The monoclonal antibody against allergic encephalitis represents not only a potential treatment for MS but it also may help researchers understand more about the disease's causes, Steinman said.

The antibody binds to a set of immune cells known as helper T-cells. Normally, the immune system operates through a delicate balance of two types of T-cells, the helpers and the suppressors. But in multiple sclerosis some helper T-cells begin to attack the body's own nerve sheaths.

The new monoclonal antibody homes in on these harmful helper T-cells by recognizing a special protein, named L3T4, coating the cells' outer surfaces.

While all-human monoclonal antibodies are more desirable for medical purposes, they have been difficult to make in the laboratory and their production seems to be unstable, Herzenberg said.

In contrast, mouse monoclonal antibodies, easily made in immunized mice or in tissue culture, can be modified into the new type of mouse-human antibodies which have a good chance of getting around the patient's immune barrier, Oi said.

The researchers made the new mouse-human antibody by splicing together mouse and human genes coding for different portions of the antibody molecule.

The mouse portion of the hybrid molecule is the part of the antibody that targets and binds specific proteins on the surface of the cancer cell or autoimmune cell. The human portion is the part of the antibody that tells the patient's own immune system how to destroy the undesirable cell or substance that it binds, Herzenberg explained.

The chimeric antibody research was supported by the National Institutes of Health, the American Cancer Society, and Becton Dickinson Monoclonal Center.

The multiple sclerosis research was supported by grants from the National Institutes of Health, the Multiple Sclerosis Society, and the Kroc Foundation.

ARTHRITIS: TAMING THE GREAT CRIPPLER

It's been more than 10 years since the National Arthritis Act was passed by the U.S. Congress to place arthritis high on the list of the nation's medical priorities. Under the act a network of arthritis centers was created nationwide for the purpose of expediting the application of research results to doctors and their patients. This story describes the work of one such center. Photos available on request. **Editor.**

STANFORD—

The statistics of arthritis tell only part of the story. They give no measure of the monumental toll of human suffering, of bedridden invalids, of painfully bent spines and of disfigured bones. But even the bare figures are enough to indicate why arthritis is the nation's number one crippler.

This year alone about one million Americans will become new victims of arthritis. Another 25 million will suffer from arthritis severe enough to cause symptoms. The impact of arthritis to the U.S. economy is $14 billion a year in medical costs and lost wages. Arthritis afflicts not only the elderly but a quarter million children as well. Its most serious form, rheumatoid arthritis, often starts imperceptibly as early as 20. The most common form, osteoarthritis, is the inevitable result of age—of normal wear and tear on bones and joints.

What have we been doing about all this? As a nation we have done very little. Until recently the approach to arthritis was fragmented and controversial.

Ironically, Stanford Arthritis Center experts like James Fries believe osteoarthritis to be the most preventable.

"We are learning," he explains, "that lifestyle is important. Weight control, exercise, protection against injuries are measures one can take against predisposing factors."

As for the most severe form of arthritis, Fries puts it this way: "If you asked what happened to a patient after 20 years of rheumatoid arthritis, the typical answer would involve heredity and severity of the disease complicated by the decisions of 20 physicians who had employed 30 odd medications in some ill-defined sequence."

Complicating this further, Fries adds, have been the many tangled threads—the amount of support from the patient's family, the boss' attitude, the medical system and its high costs, and the attitudes of the patient himself.

But this is changing. During the past 10 years more study has been devoted to arthritis than in any previous time in this century. Part of this progress can be attributed to the National Arthritis Act, passed in 1974 to place arthritis high on the list of the nation's medical priorities.

Under the act, a network of 18 federally funded multi-purpose arthritis centers was established. Their purpose: to develop community programs for bringing results of arthritis research to physicians and their patients, to do new research, and to develop education programs for health professionals and patients about arthritis.

"The Stanford Arthritis Center, established as part of that network, emphasizes public education and community-based programs," says its director Dr. Halsted Holman. "We view it as a complement to the very highly developed research into the causes and treatment of arthritis at Stanford."

Holman, an immunologist and former chairman of medicine, gave up bench research several years ago. "It became clear to me," he explains, "that biomedical research alone didn't help the practice of medicine—it didn't make it more efficient, it sometimes made it more wasteful. Alternatives appeared necessary and because we were dealing with a chronic disease the participation of patients in new approaches was essential.

"We are interested in how patients in the community respond to a particular intervention—medical as well as educational—and how events in their lives influence the course of their disease."

With few exceptions, academia has been generally skeptical about the value of community health education, regarding it as a myth, Holman notes.

But now findings from a center study of several hundred osteoarthritis patients and controls explode that myth. Designed by health educator Kate Lorig, the study shows patients trained in a self-care methods course to do as well as those on common aspirin-like drugs. The training decreased their pain measurably, increased mobility, and tended to reduce use of medical services for months.

"The results are surprising," Holman explains, "but they have to be interpreted with caution until more studies are done."

Holman and Lorig suspect multiple factors to account for the improvement. "When we asked the patients what they thought was happening, they said they felt more confident and in control of their situation," Holman explains. Attitudes are crucial to healing.

To understand what helps patients cope with their disease, the center will soon begin testing a new approach with patients in the Palo Alto community. Stanford psychology professor Albert Bandura developed this approach to help people conquer their fear of snakes. His method is based on the notion of "self-efficacy," the perception that one can learn to cope with a problem that was previously unmanageable.

The Arthritis Foundation has adopted Stanford's special education program to disseminate to millions nationwide.

But Holman worries that it may be diffused too soon before it can be evaluated. "We don't know if the approach developed in a largely suburban middle-class area like Palo Alto will work on East coast urban environments where climate, transportation and other factors affect mobility and lifestyles. This must be tested," he says.

-more-

Closely linked to the arthritis center is the American Rheumatism Association Medical Information System (ARAMIS), also federally funded and based at Stanford. Directed by Fries, ARAMIS is the most comprehensive national data bank system on arthritis and related diseases ever devised.

Data on all medical and social aspects of arthritis pour in daily into the computer-based system from a 17-city network of 40 medical specialists who have monitored 22,000 patients for the past 15 years.

"The data describe enough patients and sufficient variables so that we can sort out the relative contributions of treatments applied by different doctors and systems of medical care," explains Fries.

ARAMIS work includes:

Classifying studies to define arthritis-related diseases, and development of a database for rheumatic disease with 422 variables—demography, symptoms, signs, laboratory values, diagnoses and therapies—as a uniform terminology. It has also identified patients who may benefit from treatments deemed effective, and studied toxic effects and cost-benefits of both steroidal and anti-inflammatory drugs used in arthritis treatment.

"Having a source for finding out which treatments work best," Fries says, "not only benefits patients, but helps contain medical costs."

One of the most important ARAMIS findings has been that rheumatoid arthritis accelerates mortality. Men die of the disease four years sooner than they should, and on the average women die 10 years earlier.

This knowledge is expected to influence future therapy, especially when effective drugs with dangerous side effects are the only course. "Until recently such drugs have been used conservatively," Fries says. "Now decisions to use them may depend on trading off disability versus mortality."

While the network of centers like Stanford's and ARAMIS are transforming understanding of clinical aspects of arthritis, its causes remain obscure. The Great Breakthrough against arthritis is not imminent either. Yet the sober realist who observes the current scene is justified in cautious optimism by varied developments on the research and therapeutic fronts.

On the basic level are the studies of immunologists Hugh McDevitt, Edgar Engleman, Garrison Fathman and Samuel Strober. They are generally trying to understand the regulation of immunity, and use that knowledge to modify the body's immune response. This is important because in the inflammatory forms of the disease, like rheumatoid arthritis, something has gone awry with the immune system.

Defender cells that are supposed to protect the body from infections caused by foreign microorganisms suddenly turn against "self" cells, those of the cartilage membrane lining the inside of joints. Potent antibodies damage the membrane, causing inflammation.

Two main approaches are being considered. One is the use of tailor-made monoclonal antibodies directed against regulatory molecules on the cell surface to block the undesirable immune response. The second is total lymphoid irradiation pioneered by the late Henry S. Kaplan at Stanford. Radiation is believed to work because it suppresses the immune system activity that causes the inflammation.

In tests Strober conducted at Stanford University Hospital, 11 patients with rheumatoid arthritis were given a relatively low dose of radiation over five weeks. The patients were people regarded by their doctors as

having failed all conventional treatments and were candidates for drastic therapy with toxic drugs. Nine of the patients showed "marked improvement" including a reduction in morning stiffness, pain, tenderness and swelling, and greater ease in moving about. There was a general slowdown of the disease, which persisted throughout a 13-28 month followup. Only one patient suffered a relapse after a year.

The radiation technique is now being expanded to treatment of patients with lupus, another arthritis-related condition.

While radiation treatment is still limited to the most difficult cases, Strober says his views may change because of the latest findings which show rheumatoid arthritis to be more lethal than previously recognized. "We may have to reassess how vigorously we want to use radiation in the future," he adds.

Meanwhile, according to Fries, a new form of gold, an effective drug used in rheumatoid arthritis treatment, has been synthesized and will soon become available. "The new gold can be taken orally," he explains. "It's expected to avoid the side effects on the skin and kidney associated with gold administered by injection."

Many effective drugs like gold and penicillamine as well as steroids will continue to be used for arthritis treatment, Fries explains, but in the future, through information available from ARAMIS, doctors will be better able to match toxicity to the susceptibilities of the particular patient.

Through the center, increased attention has also been concentrated on surgical treatment for arthritis—total joint replacement. The work has been directed by orthopedic surgeon Dr. David Schurman who keeps track of over 1,200 total joint replacements performed at Stanford since 1971.

Like ARAMIS, Schurman has developed a similar computer-based system for evaluating the methods, costs, tools and results of joint replacement surgery. His system called SOAR (Standard Orthopedic Arthritis Record) has now been been adopted by the Hip Society involving about 40 of the nation's leading orthopedic surgeons and by hospitals at Harvard, UCLA, and Minnesota.

"It's a language that all surgeons in this field can use," Schurman says of the system. "As a practically oriented specialty of medicine, it's natural for orthopedic surgery to take the lead in technology assessment."

The center is also working with Dr. John Miller of the department of pediatrics and director of the rheumatology unit at Children's Hospital at Stanford. Research into juvenile rheumatoid arthritis is complicated by the appearance of the disease in children, and a lack of a positive test for rheumatoid factor applicable to children.

Studies to identify the differences between adult and juvenile rheumatoid arthritis are under way.

More recently, the arthritis center in collaboration with the Stanford Heart Disease Program, is beginning a five-year federally funded study of factors which help or hinder the development of arthritis. Among factors to be scrutinized are family history, exercise, diet and injury.

"This is a project of great importance to the health of all people as they grow older," say its directors William L. Haskell and Fries.

VOLUNTEERS NEEDED FOR CHOLESTEROL-LOWERING STUDY

STANFORD—

Guar gum, a dietary fiber offering the potential to reduce heart disease by lowering blood cholesterol, is being tested at Stanford University Medical Center.

"The potential benefits of this supplement are enormous, because it offers the promise of helping people to lower their heart disease risk simply by using a dietary additive that is a natural product," said Dr. Robert Superko, medical director of the Stanford Center for Research in Disease Prevention's Lipid Research Clinic, which is conducting the investigation.

An eight-year study completed at Stanford and eight other North American research centers concluded in January 1984 that lowering blood cholesterol levels significantly reduces the risk of heart attack or other coronary disease.

Superko said he is looking for healthy men, not more than 20 percent overweight and aged 25 to 70, who will receive a blood test. Those men found to have moderately elevated levels of blood cholesterol will be eligible to take the supplement.

Forty-eight participants will take liquid and wafer supplements for four weeks each. Half of the men will receive guar gum, while the other half will receive a placebo resembling the potentially beneficial fiber.

At the end of the study, researchers will compare the volunteers' cholesterol levels to learn if the guar gum is effective, and if so, whether the wafer or the liquid works and/or tastes better. Blood tests will be run at four week intervals to monitor progress, Superko said.

Participants will also receive information about cholesterol lowering through dietary changes, and volunteers will periodically monitor their eating habits during the study with a computerized assessment program, he said.

Jan. 15, 1985

-more-

Unknown, said Superko, is the precise way in which guar gum helps lower cholesterol, fatty deposits in the blood which tend to clog or damage blood vessels. One theory is that the fibers coat the intestines and retard absorption of the fats, he said.

Volunteers must be healthy, have stable eating habits (at least two meals per day) and intend to keep doing the same amount of exercise during the study. Blood cholesterol requirements vary for age and weight, "but we're generally looking for people with moderate levels—not high enough to administer medication but high enough so that reduction might significantly reduce their risk of coronary disease," Superko said.

Benefits for the patient include education about lowering cholesterol, blood tests and information on the role of diet in reducing the chances of heart attack.

Potential side effects include minor stomach or gastrointestinal upset, Superko said. Guar gum has been tested previously in human volunteers and extensively in rats, he added.

Patients will be asked to make six visits to Stanford for an organizational meeting, blood tests and collection of diet questionnaires.

For further information, call Lisa Sawrey-Kubicek, Wednesday through Friday between 2 and 4 p.m., (415) 497-6254, or leave a message at the same number during business hours.

The study is funded by the Shaklee Corp. of San Francisco, which manufacturers guar gum as a diet supplement.

SMASH LECTURES AT STANFORD

STANFORD—

The winter 1985 S * M * A * S * H lecture series at the Stanford University School of Medicine begins Jan 11.

The series — whose full name is "Stanford Medical and Scientific Highlights"—is open to the public and will be held in the Fairchild Auditorium, at 4:30 p.m., followed by refreshments.

The season's lectures are:

- Jan. 11: "Growth and Growth Factors," Dr. Raymond Hintz, professor of pediatrics;
- Jan. 25: "Sex and Drugs: Physiology and Behavior," Dr. Julian Davidson, professor of physiology;
- Feb. 8: "Muscle Building and Muscle Bound: Activation and Expression of Muscle Genes," Dr. Helen Blau, assistant professor of pharmacology;
- Mar. 8: "Yeast Chromosomes: Centromeres, Spindle, Segregation, Meiosis, Recombination, Rearrangements and Isolation," Dr. Ronald Davis, professor of biochemistry.

The SMASH organizing committee intends to encourage an exchange of ideas and provide a forum to inform the community about significant medical research and developments at Stanford. The Friday talks are geared toward all those with basic scientific understanding.

The lectures started in 1980 by the medical school's Faculty Senate, which now cosponsors it with the Stanford Medical Students Association.

PALO ALTANS OPEN HOMES TO STANFORD PATIENTS, FAMILIES

STANFORD—

When Kay Hardwick came from Alabama to Stanford University Medical Center to become it's 318th heart transplant patient, she wanted her mother, husband and two sons with her.

Thanks to the hospitality of Palo Altan Alice Green, Hardwick's family was able to be with her throughout her ordeal.

Green is one of a handful of local residents who, for almost no reimbursement, welcomes into her home patients coming to Stanford from out-of-town for long term treatment. Their families often accompany them and like Hardwick's boys, who are attending local schools, carry on their lives as normally as possible.

It's like having a big, extended family, Green said of the estimated 150 house guests she's had in her home over the past seven and one-half years. A Brazilian medical student who came here for cancer treatment, for example, "is my South American daughter," she explained. "Everyone is real interesting, and they make good use of my home. And the need is there."

It certainly is, agreed Susan Weisberg, clinical social worker at Stanford University Hospital. She and her colleagues receive as many as four requests each week from people who have to be in the area for outpatient treatment—primarily for cancer—but can't afford to stay in hotels.

"Being able to stay in someone's home adds another dimension to patients' treatment," Weisberg said. Green and the four other citizens who house the patients "really help the patients get through it. The results are extremely positive," she added.

It was at church that Green told Margaret Weiderholt about the need for homes for patients. Five years ago, after Weiderholt's mother moved to a nursing home, she decided to give it a try. Now, she said, she has someone with her all the time. She even finished the top floor of her small Palo Alto home to make space for another patient or two.

"It's rewarding. I get a great deal of pleasure out of helping people," Weiderholt said. "You become a mother figure or a sister figure to the people who stay with you," she explained. "People tend to lean on me, but I can lean back too.

"When my guests come I say, 'while you're here your job is to make me happy. The way to do that is to feel at home, to be at home and to make the whole house your home. If there's something you're not comfortable about, tell me."

-more-

But, she quickly pointed out, she does have her limits. Protective of her recently-refinished dining room table, she tells her guests: " 'There was a lady here who had a broken leg. I told her if she put anything hot on this table to ruin the finish I'd break her other leg.' They don't forget that, and I've never had a problem," she said chuckling slyly.

Her guests love to help her out, especially when they realize she is sometimes limited because of arthritis, Weiderholt continued. An Oregon lumberman who stayed with her, for example, cut down some trees in her yard for her. The garbage always gets taken out, and the paper brought in, by her guests. And on the mornings her arthritis causes difficulty in making the bed, a guest is usually there to help.

"The people are really wonderful,"Weiderholt said. "They've renewed my faith in the human spirit and its resilience and capacity for using available resources. And, I'm convinced that people who have some kind of faith in something beyond themselves are better able to cope.

"The manner in which they seem to be able to handle their disease is impressing," she continued. "Some of them keep on going and affirm life. They keep up with activities and postive pursuits.

"The Oregon lumberman, for example, was told by his doctor that he had cancer and two months to live. His wife said he just cried and cried—he thought it was the end of the world. That was five years ago. Being at a place like Stanford, where everyone is highly encouraging and not defeatist, makes all the difference."

"I had a young couple here last summer," Green added, "and the man had a rare form of cancer. He was a skier and owned a resort. He had been told he wouldn't be able to go back to any of that. Well, I just had a note from him the other day, and he's jogging and skiing and doing great."

"They're all special," Weiderholt reminisced. She fondly remembers two ladies who stayed with her at the same time. At odds when they first met, she said, the three of them quickly became "cronies.

"We cooked together, we went shopping together, we laughed until our sides were sore," Weiderholt said. She still hears from one of the ladies; the other died about a year ago.

"Alice (Green) asked me one time how many people I had lost," she continued. "That means that when one of our house guests dies, it's a personal loss for us. The best way to deal with death is just to be a good listener, and to convey to the patients and their relatives that you are feeling for them."

About a year ago, for example, a patient's wife and son were staying with Green. "I was up and waiting for them when they came home after the man died," she recalled. "You just have to be able to give a lot of support, comfort and let them cry."

Most of the stories about their guests, however, have happier endings. Green and the Hardwick family were out to lunch when Kay realized she had left home the beeper that all heart transplant candidates must carry so the hospital can notify them the moment a heart is available. Sure enough, when they got home the beeper was sounding, and everyone piled back into the car to take her to the hospital.

"She saved our lives," Hardwick, who is nearly ready to return to Alabama after a successful heart transplant, said about Green. "Without her, my family wouldn't have been able to be with me. And that's made all the difference."

VOLUNTEERS NEEDED IN DIABETES DRUG STUDY

STANFORD—

Researchers at Stanford University Medical Center are seeking volunteers to help learn if an oral medication will help control diabetes.

Men and women ages 25 to 75, who have adult onset diabetes and are taking insulin, are needed. They should be in good health and not taking other medications.

The study, conducted under the direction of Dr. Gerald Reaven, professor of medicine, will add glipizide to the insulin treatment. Glipizide (or Glucotrol) is an oral hypoglycemic only recently released in the United States for the treatment of adult onset diabetes, said Dr. Elizabeth Fraze of Stanford's clinical research center (CRC).

Researchers hope that diabetic patients who have not previously succeeded on oral medications may eventually be controlled with this pill, Fraze said, alone or in combination with insulin.

Participants in the study will receive free physical examinations with complete medical history, electrocardiogram, urinalysis, and blood tests to evaluate kidney and liver function, cholesterol, and blood sugar.

Volunteers accepted into the program will initially spend about three days in the CRC, followed by approximately weekly visits for the duration of the study.

For information, call Fraze or Dr. Arthur Swislocki at (415) 497-6973.

FASTING RATS' ABILITY TO DIGEST PROTEIN COULD HAVE IMPLICATIONS FOR STARVATION IN HUMANS

STANFORD—

Contrary to popular wisdom, a slow return to eating following starvation or prolonged fasting may not be medically necessary, says a Stanford University Medical School scientist.

New laboratory studies in rats have shown that one portion of the digestive system that is suppressed during fasting responds almost immediately to the presence of food, said Dr. Gary Gray.

"Our studies suggest that the standard practice of gradually phasing starving individuals back to a normal diet may needlessly prolong malnourishment," said Gray, a professor of medicine and chief of gastroenterology at Stanford University School of Medicine.

Potentially, the work could lead to further research with implications for physicians dealing with severely malnourished populations, such as in Ethiopia, Gray suggested.

Gray reported his findings about rats in an article in the January 4 issue of *Science* magazine with colleague Dr. Ann M. Reisenauer, a postdoctoral researcher now on the faculty of the University of California at Davis.

However, he cautioned that although the rat digestive system provides a good model for human digestion, more research is needed to determine precisely how the human system responds to food following starvation and which foods are best tolerated.

"This is an area in which not enough research has been done," Gray commented. The practice of gradually reintroducing food is based on observations that starving people sometimes cannot readily tolerate food.

The researchers studied an intestinal enzyme called amino-oligopeptidase (AOP), involved in the digestion of proteins. AOP acts on protein fragments from food that has been broken down by enzymes higher in the digestive tract. It breaks these fragments into smaller peptides and amino acids, nutrients that can be absorbed by the body.

In food-deprived rats, levels of this enzyme fall very low. But what Gray and Reisenauer found is that the enzyme begins returning to normal levels much more quickly than previously thought—within 20 minutes after protein fragments reach the intestine.

"The evidence indicates that at least one enzyme involved in digesting peptide nutrients is dormant and ready to be synthesized as needed once food becomes available," Gray said.

Because AOP acts only on protein that is already partially digested, the findings also suggest that food preparations containing partially digested protein may be a good food source for starving people, said Gray.

Whole protein may not be assimilated well, Gray said, unless enzymes higher in the digestive tract are also quickly recruited into action in the presence of food.

For this reason, it might be worth studying commercial preparations of partially hydrolyzed, or digested, protein as a first food source under starvation conditions.

The research was carried out with grants from the National Institutes of Health.

BASIC SCIENCE RESEARCH LECTURES PLANNED

Editors, writers: While these talks are intended for medical and technical professionals, and not the general public, science and medical writers are welcome to attend for background or coverage.

STANFORD—

The 1985 winter-spring basic science research colloquia at Stanford University Medical Center are:

- Jan. 16: "Actin and myosin; molecular approaches to the study of cell motility," Dr. James Spudich, professor of cell biology;
- Jan. 30: "Reconstitution of intracellular protein transport," Dr. James Rothman, professor of biochemistry;
- April 17: "Molecular strategies of microbial pathogenicity," Dr. Stanley Falkow, professor and chairman of medical microbiology;
- May 22: "Transduction in rods and cones," Dr. Denis Baylor, professor of neurobiology.

The Wednesday talks are all to be held 4:15 p.m. in Fairchild Auditorium at the medical center. A reception will follow each lecture.

MODERNIZATION CONSTRUCTION INCREASES AT STANFORD UNIVERSITY HOSPITAL

STANFORD—

About 4,000 truckloads of dirt will be moving away from Stanford University Medical Center during the next three months as part of the hospital modernization program, said the HMP's Elvia Garwood.

The dirt will be replaced with a structure housing a center for nuclear magnetic resonance, a state-of-the-art form of X-ray which provides detailed diagnostic pictures without radiation. Also to be located in the lower level where dirt now sits will be 52 patient beds, a pharmacy, and a variety of support facilities, said Garwood.

But before construction can begin on the new Stanford University Hospital (SUH) addition, about 80,000 cubic yards of dirt must be removed from the site, wedged between the current hospital and Blake Wilbur Drive.

Garwood said that 25,000 cubic yards of dirt will be stored on 12 acres of land along Quarry Road near the present hospital parking lot, while the rest will be hauled away as fill in various locations.

Each truck will carry about 20 cubic yards, said Garwood, mostly betwen 7 a.m. and 3 p.m. She said traffic on streets near the medical center could be affected during the morning "but conditions should be completely clear by the afternoon commute."

During January, construction activities of the $112 million renovation include:

- A waiting area used by families of surgery patients is being relocated to a new site above the emergency room adjacent to room P2000. Families of patients will be directed to the area.
- A construction fence has been set up around the work area, causing some detours for pedestrians entering or exiting the hospital enroute to several parking lots, the cardiovascular research building, the administrative services annex or Welch Road offices. Alternative parking lot entrances have also been designated for several lots along Blake Wilbur Drive. A new 191-space C parking lot, with an entrance on Welch Road and direct pedestrian access to the hospital, was opened in December.
- The community relations office, including patient relations, will be moving from room P3018 to P2020D, and the medical staff office, including the chief of staff's office, will be moving temporarily in January from P3016 to P1060. Phone numbers will remain the same, and signs will redirect persons to the new previously unoccupied locations. "These two offices have been carved into what originally was intended as a corridor. The construction will turn the area back into a hallway leading from the existing hospital to the new building," Garwood said. Both offices will be relocated to new space when construction is completed.
- Construction activities in several units may produce noise which patients may hear, particularly in the west wings of the hospital. "We'll even give earplugs to patients and their families if they need them," said Garwood.
- Emergency fire exits serving the east end of the "P" building will be temporarily relocated. Garwood said signs will be posted. The move is not expected to affect patients, since the stairway—formerly used for routine traffic—did not serve patient areas.

The project, intended in part to ensure that newly developing technology can be implemented at SUH, is expected to be completed by December 1987.

FREE COURSE TEACHES CANCER PATIENTS TO COPE

STANFORD—

A course developed by the American Cancer Society to help people deal with cancer will be offered at Stanford University Medical Center on eight consecutive Wednesday afternoons, starting Jan. 16.

Nutrition, body image, rehabilitation, and sexuality are among the topics covered by the course, called "I Can Cope," which is intended for cancer patients and their families, says co-leader Beverly Zenk Wheat, R.N.

The course deals with daily health problems as well as legal and work issues. Free of charge, it will be taught by a team of Stanford oncologists, nurses, dietitians, physical and occupational therapists, social workers, and other guest speakers. Information about and access to appropriate community resources will be provided.

"Participants in this course are given an opportunity to realize they are not alone in their adjustments to everyday life," according to Zenk Wheat. "Those with cancer and their loved ones need ways to cope with fears and anxieties as well as the disease."

Implemented nationally, she said, the patient education program is helping move people from asking, "What can I do?" to stating, "Here's what I can do!" The course supports the premise that increased knowledge about cancer decreases anxiety and increases a personal sense of participation on the part of the patient and his or her "significant others," with the medical system.

The course was developed by Judi Johnson, R.N., and Pat Norby, R.N., for the Minnesota Division of the American Cancer Society.

Sessions will be held from 3:30 to 5:30 in the Darwin Library, room C122 in the medical center. Susan Weisberg, L.C.S.W., Miriam Beinin, L.C.S.W., and Zenk Wheat, will co-lead.

For information and registration, call the department of clinical social work by Jan. 14, at (415) 497-5091, or Beverly Zenk Wheat at (415) 497-5397.

PROGRAM FOCUSES ON CARE OF MOTHERS AND INFANTS

STANFORD—

"Perinatal Potpourri: Reaching Out and Looking Forward" is the title of the fifth annual meeting of the Mid-Coastal California Perinatal Outreach Program (MCCPOP).

The meeting, sponsored jointly by Stanford's and Santa Clara Valley Medical Center's (SCVMC) departments of gynecology and obstetrics and pediatrics, will be held on Jan. 10 and 11 in Monterey at the Doubletree Inn. It is open to the public.

Lectures include "Levels of Perinatal Care: Maximizing Utilization and Outcome," "Clinical Management of Post Term Pregnancy," "Current Research: Fathers and Childbearing," and "Nutrition for the High-Risk Mother."

Stanford faculty will be joined by nutritionists, administrators, and specialists from SCVMC, other hospitals, and private practice.

The program has been designed to provide physicians, nurses, and other perinatal health care providers with the most current information on frequently encountered problems in the care of mothers and infants, says Kim Leadon, administrative assistant.

MCCPOP has developed educational programs throughout an eight-county region (San Mateo, Santa Clara, San Benito, San Luis Obispo, Monterey, Santa Cruz, Stanislaus and Alameda). The program includes a perinatal resource center, a genetic counseling center, and a birth defects center, as well as providing emergency consultation and transport, perinatal nursing internships, and intensive care nursery internships.

For the upcoming program there is a registration fee which will include all conference materials, instruction, refreshment breaks, reception and Friday's breakfast and luncheon. A block of rooms has been reserved at the Doubletree Inn.

The program has been approved for continuing education.

For further information call Kim Leadon at (415) 497-5763.

SELF-HELP COURSE/CLINIC OFFERED FOR PSORIASIS

STANFORD—

A free self-help clinic designed to help persons with psoriasis learn how to cope better with their lifelong problem has been scheduled at Stanford University Medical Center starting Jan. 10.

Psoriasis, a skin ailment often characterized by thick, red scaling plaques, poses treatment dilemmas because there is no known cure for the itching discomfort and treatment is often prolonged, said Dr. Lexie Nall, senior research associate and director of the course.

Four two-hour classes, intended for patients and their families, will be held on consecutive Thursdays in the Edwards Building, room R136, in the Medical Center. Physicians or other professionals who work with psoriasis patients are also invited.

The clinic, which includes lectures on genetics, preventive measures and treatment, as well as discussion groups and written information, is being supported at no cost to the patient by the Psoriasis Research Institute of Palo Alto.

Psoriasis is caused by some form of cellular hyperproduction, although treatment is frustated because the mechanism of the disease is poorly understood, the researcher said. The course of the disease is unpredictable, and recurring flareups can be particularly stressful for patients, she said.

Psoriasis is a worldwide problem which can be triggered in genetically predisposed persons by a variety of factors, such as injury to the skin, sun, prolonged low humidity or medications. It is not contagious, she added.

The clinic includes information about the cause and course of psoriasis, treatment, preventive measures, myths, and research. It is taught by Nall and Brigid O'Connell, research fellow, who may be contacted for further information or registration at (415) 497-7967.

HEWLETT-PACKARD OFFERS CORPORATE

CHALLENGE GRANT TO STANFORD HOSPITAL MODERNIZATION

STANFORD—

Hewlett-Packard Co. (HP) has offered a $250,000 challenge grant to area corporations to support Stanford University Hospital's $112 million modernization project (HMP), the hospital and the Palo Alto-based company announced Wednesday (Jan. 2).

John Young, HP president and a Stanford trustee, said his company would contribute $1 for every $4 raised from other corporations. If the $1 million goal from other corporations is met, HP will make its maximum commitment of $250,000, bringing the total to $1.25 million.

The challenge grant was announced at the same time Stanford President Donald Kennedy said a fundraising committee of prominent corporate executives had been established to raise a minimum of $1 million toward the project's $15 million fundraising goal.

Appointed by Stanford to head the hospital modernization fundraising effort was Richard G. Rogers, president and chief operating officer of Syntex Corp. of Palo Alto.

Kennedy said Rogers will be assisted by three division chairmen, Albert Eisenstat, vice president and general counsel of Apple Computer, Cupertino; Jack Black, Central California vice president for Pacific Bell in San Jose; and James W. Morrell, executive vice president, Saga Corp., Menlo Park-based national food supplier.

Rogers said Eisenstat will work most closely with the electronics industry, Morrell with the industrial sector, while Black will work predominantly with service businesses such as his own.

Kennedy, who also serves as chair of the hospital's board of directors, said the hospital modernization is intended to upgrade and consolidate patient care and will be financed by a public sale of bonds, as well as contributions.

"This is the first time that Stanford University Hospital has turned to our business neighbors in an active way to seek support for facilities we need to continue our role of providing outstanding medical care to our neighbors," Kennedy said.

-more-

Jan 2, 1985

The corporate committee is one of two external groups established recently to help lead the fundraising effort. The other group is 10-member steering committee representing the 1,200 community physicians who admit patients to Stanford University Hospital and play an integral role in the patient treatment and academic missions of the hospital, Kennedy said. That committee is headed by Palo Alto physician Alfred P. Spivack.

Another Hewlett-Packard executive, Dean Morton, executive vice president and chief operating officer, was appointed last month as chairman of a volunteer leadership committee for the $145 million fund-raising program to support medical center capital projects and endowment, including the hospital modernization. Morton is a member of hospital's board.

"Stanford University Hospital is a special hospital, a unique asset to the nation and most particularly to those of us who live and work in the area," said Young. "We feel so strongly that the academic medical resources of Stanford need and deserve corporate support, that for the first time we are providing a substantial cash commitment in the form of this challenge."

Rogers said, "For many years I have worked actively with several medical institutions in our community to help them find the resources they must have to deliver needed health care to our neighbors. Each of these institutions has a vital role, but I approach this assignment with particular pleasure because of Stanford Hospital's incomparable service to this community—and indeed the entire nation."

Rogers cited SUH statistics showing that about 70 percent of the hospital's patients live in San Mateo or Santa Clara County, while more than 80 percent live in the Bay Area.

"The new life-saving knowledge being generated at Stanford to conquer disease and prolong healthy lives is often applied first in our community through the services of Stanford University Hospital," he continued.

"Put simply, this hospital exists to provide a level of care that other community hospitals can not," Rogers added.

Kennedy said the modernization project, currently underway and scheduled for completion in 1987, will provide 20 new operating rooms, and two new four-story wings of patient beds. While no beds are being added to the current total of 663, the project will allow an increase in the average square foot per bed from 891 to 1,387, near the average for teaching hospitals throughout the country.

"Flexible new intensive care units will permit sophisticated observation of individual patients by nurses at central monitoring stations," Kennedy added.

GOVERNMENT REPORT URGES SUPPORT OF MENTAL HEALTH RESEARCH

STANFORD—

Mental health research funding in the United States should be doubled within five years, since current funding has fallen short of the needs and potential of this promising field, concluded a recent report of the Institute of Medicine (IOM).

The IOM's Board on Mental Health and Behavioral Medicine, chaired by Dr. Jack Barchas of Stanford University, said behavioral problems account for 50 percent of the mortality from the top 10 causes of death. The panel said the total cost to society of mental illness and addiction—not counting the emotional toll—amounts to $185 billion a year.

"Mental disorders, alcoholism, and drug addictions profoundly disrupt the lives of 30 to 45 million people in the United States each year, with conservative estimates of annual expenditures for direct health care at $20 billion," the report stated.

Barchas, in a recent interview, said biological and neurochemical findings over the past decade, as well as advances in the psychosocial sciences, give hope of rapid strides in the prevention and treatment of mental illness—given adequate research funding. Continued basic and applied research related to mental and addictive disorders is crucial, using the full range of tools available in the biological, social, and psychological sciences, the report said.

The report recommended a doubling, at least, of federal funding of the institutes in the Alcohol, Drug Abuse, and Mental Health Administration (ADAMHA). This would amount to a budget of $500 million in 1983 dollars, by 1989. ADAMHA's research budget in 1984 was $273 million.

Barchas, the Nancy Pritzker Professor of Psychiatry and Behavioral Sciences, said this is the first time an IOM report has recommended a specific target expenditure within a set number of years.

"Many feel our recommended figure is still quite conservative, that it should be a billion dollars," he said. Institutes in the National Institutes of Health (NIH) have grown more rapidly over past decades, while ADAMHA "has fallen behind by 50 percent compared with 20 years ago in terms of real spending power, even as research opportunities and the number of qualified scientists have grown," he said.

"Severe depression, anxiety, schizophrenia—these are real diseases with lots of pain and discomfort," Barchas continued. "You can't just tell people to shape up and get ahold of themselves. I've seen people about to commit suicide who had been told such things."

But the tremendous stigma against both patients and researchers in mental health results in a lack of the type of broad political support that there is for cancer or heart disease research, he explained.

"So these families suffer in silence."

Research has already pointed to the important role of psychiatric disturbances in many physical illnesses, Barchas said. Still, for every person with cancer, nearly $200 is spent annually on research. For each person with a severe mental or addictive disorder, the figure is less than $10.

-more-

The committee found widespread childhood mental disease, as a "crime within a crime," Barchas noted. "There are as many children with autism as there are with leukemia," he said, "but you don't hear about it. Nor is enough research being done on hyperactivity, childhood depression, or other illnesses."

There are at least 3 million teen-age alcoholics in this country, added to 10 million adults, Barchas said. For every alcoholic however, only $2 is spent in research each year. Drug abuse commands a similar expenditure.

"We like to think of ourselves as a child-oriented society. In some ways it's true, but in other ways it's nothing but a myth," Barchas said.

The report said that some illnesses "typically have a costly, chronic course, so even relatively small advances can result in enormous direct and indirect savings for society."

"We (the committee) were asked specifically about research," said Dr. Glen Elliott, a Stanford research physician who co-chaired the IOM committee. "The other issue is the need for improved treatment facilities. The recommended research funding is a mere pittance compared to the money such research can save in the future as a result of more effective treatments," he added.

Statistics have shown that during any six-month period, 19 percent of the U.S. population suffer from some psychiatric disorders. Yet only 20 percent of the affected group seek treatment, for a variety of reasons.

Another recommendation of the report was that more academic medical centers should be developing clinical research centers in mental health, Barchas said. (*Stanford has one of the few such existing centers—Editor.*)

"We need to assemble, nationwide, a critical mass of faculty backed by adequate resources and high technology equipment," Barchas said. In addition, the report calls for an increase in the training of M.D.-Ph.D. physician researchers.

Also co-chairing the IOM committee from Stanford were Dr. Philip Berger, the Kenneth T. Norris Jr. Professor of Psychiatry and Behavioral Sciences, and Dr. Patricia Barchas, assistant professor of sociology. Dr. Ruth Gross, professor of pediatrics, and Dr. Roland Ciaranello, head of the division of child psychiatry, also participated on the preparation panel.

The board consisted of representatives from many different institutions throughout the country and from many intellectual disciplines, Barchas said. More than 300 scientists in the psychological, social, and biological sciences contributed to the report.

Barchas said that no one administration is entirely to blame for the research underfunding, which "has occurred over the years without being challenged."

So far, Barchas and Elliott said, response to the report has been very positive. The *American Journal of Psychiatry* plans to publish it as a supplement. The two physicians have been asked to brief Congressional staffers, and possibly to testify before the U.S. Senate.

The committee members said they hope the report will serve to create greater awareness of research opportunities for both the short and long term.

"There seems to be an emerging consensus of broad need," Barchas said. "The exact timing for increased spending will probably be the real question," he said, with concern over the federal deficit causing the Office of Management and Budget to cut NIH spending and to consider reorganization in many fields.

"It was marvelous to us that the report was requested at all, by top people in the federal government," Barchas noted. "It's clearly an issue that goes beyond party politics. It has to do with a personal concern for humanity."

STUDY NEEDS MALE RUNNERS

STANFORD—

Healthy male runners, ages 20 to 50, are needed to participate in Stanford University Medical Center studies examining the relationship between physical training and glucose (blood sugar) utilization.

Volunteers must be capable of running 10 kilometers in less than 40 minutes, said Ken Rodnick, graduate research assistant.

Participants will be required to spend three to four half days in the Clinical Research Center at Stanford and will receive a free complete physical examination, including an oral glucose tolerance test, measurement of VO2max (maximal aerobic capacity), measurement of percent body fat, metabolic studies looking at glucose utilization, and a fat tissue biopsy.

The studies are being conducted under the direction of Dr. Gerald Reaven, professor of medicine.

For more information contact Rodnick, weekdays between 8 a.m. and 5 p.m., at (415) 497-6973.

CORONARY BYPASS OPERATIONS OFTEN UNNECESSARY, STANFORD STUDY SHOWS

STANFORD—

Coronary bypass operations are only "temporary solutions" that could be avoided in many patients who undergo the procedure to relieve chest pain and prolong life, according to a Stanford University Medical School researcher.

These findings, based on the results of a recent study on the benefits of bypass surgery, are just beginning to affect the annual number of coronary bypass operations. The surgical procedure is still the most often performed, costing about $3.5 billion each year, according to the American Heart Association.

The number of bypass operations declined by 7 percent in 1982, after increases of 16 percent in 1981 and 20 percent in 1980, the association reported.

"There are quite a few unnecessary bypass operations taking place," said Dr. Herbert Hultgren, Stanford professor of medicine and medical co-director of the 11-year-long Veterans Administration study, which included patients at the Palo Alto Veterans Administration Medical Center and 12 other VA hospitals throughout the country.

The study showed that only 20 percent of angina patients who fell into specific high-risk categories had improved survival from coronary bypass operations, Hultgren said. The majority of patients fell into low-risk categories and did best when treated medically with drugs for as long as possible.

The coronary bypass procedure was developed in 1967 as a way to surgically bypass coronary arteries blocked by the accumulation of fatty material, a disease known as atherosclerosis. The blocked arteries reduce the flow of blood that carries oxygen to the heart, which causes chest pain.

2-27-85

-more-

Based on the study, when a patient complains of chest pain, Hultgren explained, he should be evaluated by simple non-invasive methods to see if he does in fact fall into one of the high-risk categories, which includes patients suffering from left main coronary-artery disease, three-vessel disease with impaired heart function and who have a history of hypertension, heart attack or abnormal electrocardiograms. If he does not fall into these high risk groups, he should not undergo a bypass operation unless medical treatment fails, Hultgren said.

The reason, he continued, is that the study showed that as soon as 10 years following the first operation, the grafts bypassing the occluded arteries start to close up. This usually necessitates a second operation.

"Most bypass operations are done to improve the patient's quality of life and relieve chest pain," Hultgren said. "But the study shows this can often be done with medication. This means that physicians must now ask themselves not only if they should operate but when.

"Physicians should not recommend surgery in low-risk patients if the patients can be controlled with medication for as long as possible."

The study, reported in a recent issue of *The New England Journal of Medicine* showed that for 686 patients treatment did not affect survival rates after 11 years. About 57 percent of those treated medically survived, compared with 58 percent of those treated surgically.

"Those patients with a high risk of dying benefit from surgical treatment, but beyond seven years the survival benefit gradually diminishes," concluded Hultgren and colleagues in the report.

The researchers plan to follow the patients for a total of 15 years, Hultgren said.

The study is similar to two others conducted by the National Heart, Lung and Blood Institute and a European group, but has the longest follow-up results. All three studies, however, reach essentially the same conclusions, Hultgren said.

STANFORD MEDICAL SCHOOL RESEARCHER WINS PASSANO YOUNG SCIENTIST AWARD

STANFORD—

Dr. Mark M. Davis, assistant professor of medical microbiology at Stanford University School of Medicine, has been selected to receive the 1985 Passano Foundation Young Scientist Award.

Davis, 32, is being recognized for his "central contributions to the understanding of the most fundamental aspects of the immune process," the Foundation announced.

He will receive the award and a $10,000 honorarium at the Passano Foundation's award presentation dinner in Baltimore on April 1.

Davis' research is helping to explain how the immune system fights cancers, viruses, and bacteria, and how it controls tissue rejection.

His present work focuses on T-lymphocytes, cells that help regulate the body's overall immune response and are themselves involved in combating viral infections, cancers, and in rejecting transplanted tissue.

In particular, Davis and his colleagues have isolated genes that direct production of the T-cell receptor, a protein that helps the immune system recognize abnormal or foreign cells.

His work recently enabled researchers from the Wistar Institute in Philadelphia to find a connection between a human T-cell receptor gene and a chromosome region linked to certain cancers. This could lead to information about how T-cell cancers develop, Davis said.

Davis obtained his bachelor's degree from the Johns Hopkins University in Baltimore in 1974 and received his Ph.D. from the California Institute of Technology in 1981.

Before joining the Stanford Medical School faculty in 1983, he was a fellow in the Laboratory of Immunology at the National Institutes of Health in Bethesda.

Beginning in 1945, the Passano Foundation has presented an award each year to a person or persons who have made an outstanding contribution to the advancement of medical sciences and whose work was done in the United States. The Foundation's directors give prime consideration to work that has immediate clinical value or gives promise of practical application in the near future, the Foundation said.

Founded by the late Edward Boteler Passano, then chairman of the board of the medical publisher, The Williams and Wilkins Co., the Foundation has honored more than 50 scientists.

The 1985 Passano Foundation Senior Laureate is Dr. Howard Green of Harvard University, who is being honored for his contributions to cell biology, including the development of methods for cultivation of human skin and its successful use in severely burned patients, the Foundation said.

Previous Stanford Medical School recipients of Passano awards are Drs. Hugh McDevitt and Roger Kornberg.

VACCINE TO PREVENT SEVERE URINARY TRACT INFECTIONS UNDER DEVELOPMENT AT STANFORD

STANFORD—

A potential vaccine to protect women against serious complications of the most common type of urinary tract infection has been developed by Stanford University Medical School researchers.

The vaccine blocks bacteria that cause urinary tract infections from spreading to the kidneys where they can cause more severe disease, the researchers said.

The vaccine, a purified protein produced through recombinant DNA techniques, has so far been proven effective in mice with experimentally induced urinary tract infections.

It will be tested in people, probably within the coming year, said Dr. Gary Schoolnik, assistant professor of medicine and medical microbiology at Stanford University School of Medicine.

The work was carried out in Schoolnik's lab by Dr. Peter O'Hanley, chief resident in the department of medicine, and Dr. David Lark, a urologist working toward a doctoral degree in medical microbiology, in collaboration with the laboratory of Dr. Stanley Falkow, professor and chairman of medical microbiology at Stanford. Schoolnik is also chief of infectious diseases at the Palo Alto Veterans Administration Medical Center.

If shown effective in humans, the vaccine would be most beneficial to women who are prone to recurrent urinary tract infections and thus identifiable as being at highest risk for complications, Schoolnik said.

But it is potentially of benefit to every woman who experiences a urinary tract infection at some time in her life, an estimated 15 percent of all women, he said.

The new vaccine is unusual in that it consists of a highly purified protein made through recombinant DNA techniques, Schoolnik said. The scientists know the exact structure of the pure protein in the vaccine as well as the structure of the gene that codes for the protein, Schoolnik said.

Schoolnik—whose laboratory just last month announced development of a potential vaccine against gonorrhea—and his colleagues reported on the new vaccine in an article published in the February issue of the *Journal of Clinical Investigation*.

Funding for development of the vaccine has been from the National Institutes of Health and from Cetus Corporation of Emeryville, Schoolnik said.

Urinary tract infections are among the most common medical problems of female outpatients, Schoolnik said, and although usually not serious, they can be a major cause of discomfort and loss of work time.

2-27-85

-more-

When a urinary tract infection is confined to the bladder, it is called cystitis, he explained. In a small percentage of women with cystitis, the kidneys also become infected, causing a condition known as pyelonephritis which may require hospitalized care and can lead to sepsis, an infection of the blood. In some patients, it can also lead to kidney failure and hypertension, Schoolnik said.

Antibiotics are an effective treatment. But in women who experience frequent urinary tract infections, a vaccine to halt recurrences would spare considerable illness while being cost-effective, he said.

The potential vaccine was tested in mice infected with a virulent strain of E. coli bacteria taken from a patient with pyelonephritis. The vaccine was effective in preventing urinary infections from spreading to the kidneys and causing pyelonephritis in 19 out of 22 mice, Schoolnik said.

Since urinary tract infections in mice provide a good model for the condition in people, Schoolnik is optimistic that the vaccine will be able to prevent pyelonephritis in patients, and perhaps cystitis as well.

In addition to sparing the patient considerable discomfort, a vaccine would be less expensive than repeated doctors' appointments and it would minimize the use of antibiotics, to which growing numbers of bacteria are becoming resistant, he added.

The vaccine works by preventing E. coli bacteria from attaching to tissues lining the insides of the bladder and kidneys. If the bacteria cannot adhere, they cannot infect the organs, Schoolnik explained.

The bacteria use tiny appendages called pili to attach to the tissues. The vaccine induces production of antibodies that block the pili from performing this attachment function, Schoolnik said.

Scientists in Falkow's lab isolated the gene that directs production of the pilus protein from a highly virulent strain of E. coli, Schoolnik explained. When that gene was transferred into a normally mild strain of E. coli, it gave the recipient bacteria the ability to attach to the kidney lining, he said.

The bacteria that received the pilus protein gene made numerous copies of it, turning themselves into tiny "factories" that produced large quantities of the pilus protein, Schoolnik said. It was from these bacterial factories that Schoolnik's laboratory purified the protein and tested it as a vaccine in mice.

Stanford University has applied for a patent on the protein that comprises the potential vaccine, Schoolnik said.

HEART, HEART-LUNG DONORS: "THE NEED IS ALWAYS THERE"

STANFORD—

Stanford University Medical Center's heart transplant program is in desparate need of donors with twice the average number of candidates waiting for the life-saving operation, said Marguerite Brown, donor coordinator.

"We have 12 patients waiting for heart transplants," Brown said. "A few have been waiting for nearly a year."

Some have been waiting for a period longer than their physicians predicted "safe," she added.

An important factor for heart transplants is to find a donor with a blood type and heart size that matches as closely as possible that of the recipient. Donors aare typically accident victims who have suffered brain death.

The last heart transplant was performed at Stanford on Feb. 9, 1985, bringing the total to 330 since 1968 with 145 survivors. In recent years physicians at Stanford have performed an average of more than three heart transplants each month.

"We're not sure why we're experiencing a lull in donors," Brown said. "Either there are no donors or people aren't aware that we need them.

"The need is always there," she added.

Stanford's heart-lung transplant program is also suffering a lack of donors, Brown continued. The number of candidates waiting for the double transplant operation has reached 21, some of whom have been waiting for nearly 2 years.

"Donors for heart-lung transplants are harder to find because we have to consider other factors such as size and weight of both donor and recipient," Brown explained. Delicate lung tissue must be healthy, she added, eliminating some donors with healthy hearts from the heart-lung program.

The last heart-lung transplant operation was performed at Stanford on Jan. 7, 1985, bringing the total to 23 since 1981 with 14 survivors.

ZIMMERMANN LECTURER DISCUSSES NERVE TRANSPLANTATION

STANFORD—

"Neural Transplantation into the Mammalian Brain" is the topic of the ninth annual George A. Zimmermann Lecture at Stanford Medical School, to be presented by Dr. Albert Aguayo, professor of neurology at McGill University, Montreal, Canada.

The event, sponsored by the neurology department, will be held at 5 p.m., Feb. 28, in room M106. The discussion is to focus on the transplantation of nerves, rather than the entire organ.

Aguayo received his M.D. at the University of Cordoba, Argentina, in 1959. He has been on the faculty of McGill since 1967. He is also head of the neurosciences unit at Montreal General Hospital. He has published widely, served in many professional societies, and received several awards. The most recent honor in 1984 named him a Fellow of the Royal Society of Canada.

Aguayo is most widely known for his experimental studies on regeneration and regrowth in the central nervous system, said Dr. Leslie Dorfman, associate professor of neurology and director of the multiple sclerosis clinic.

The Zimmermann Lectureship was established by Stanford's department of neurology in 1977. It was part of a gift for research and treatment of multiple sclerosis at Stanford, from the late George A. Zimmermann, a long-time San Francisco businessman.

MAGNETIC RESONANCE PROVIDES A NEW LOOK INTO HUMAN BODIES

STANFORD—

Stanford University Medical Center's magnetic resonance imaging (MRI) facility is scheduled to begin operation by the end of February, said Dr. Dieter Enzmann, diagnostic imaging center director.

MRI produces X-ray-like pictures that give more information about the human body than other methods. The technique does not use radiation however, making it one of the safest imaging technologies available, Enzmann said.

The new system, operated under the auspices of the Stanford's Faculty Practice Plan, is temporarily housed near the medical center at 2606 E. Bayshore, Mountain View. Only one other machine like it is available in the Bay Area, Enzmann said. Stanford University Hospital's modernization project includes plans for an MRI system to be housed within the hospital.

Until then, outpatients can go directly to the facility to have images taken, while inpatients of Stanford University Hospital will be transported there by ambulance. Appointments can be set up through the radiology department.

The 7,000-square-foot facility was modified with specially shielded walls and adequate perimeters to accomodate the MRI system, which includes a large doughnut-shaped magnet up to 140,000 times the strength of the earth's magnetic field. Without proper safety precautions, the powerful magnet could skew the mechanism of a passerby's pacemaker, or wipe out the magnetic strip on a bankteller card.

MRI is based on Stanford physicist Felix Bloch's theory of nuclear magnetic resonance, for which he received the 1952 Nobel prize. The concept behind magnetic resonance is that the body's nuclei contain magnetically charged particles that can be manipulated to give off signals that are picked up and interpreted by computers. The differences in the signals tell physicians precisely which organ in the body they are coming from, what the organ is made of and information about the organ's structure and function.

MRI tracks the body's various substances, such as its most common one, hydrogen. By doing so, physicians can see soft tissue, obscured by bone in more conventional imaging techniques, in minute detail. While CT—computer tomography—scans are limited to showing cross-sectional slices of the body, magnetic resonance imaging can be performed at any desired angle. These differences have already proved the technique a superior diagnostic method for a number of diseases, such as brain tumors, blood vessel blockages, and infectious processes, Enzmann said.

Multiple sclerosis, a central nervous system disease, is diagnosed relatively easily because of MRI's high sensitivity that distinguishes diseased tissue from normal tissue.

MRI is not limited to imaging hydrogen. Sodium, for example, provides information about the fluid in and around the brain. "It may also be useful in diagnosing strokes and tumors," Enzmann said.

The technique can better diagnose atherosclerosis, he continued, because it can detect fatty tissue building up to occlude the heart's blood vessels. It can detect cancerous lymph nodes in the central lung area, not possible with more conventional techniques that fail to distinguish large blood vessels from enlarged lymph nodes.

"It appears to be superior to other diagnostic tests in a number of other anatomic areas as well," Enzmann said. "There is reason to believe that blood vessels throughout the body can be accurately studied with MRI, thus potentially eliminating the need for some types of angiograms."

MRI also allows physicians to study the bone marrow to a degree not possible with other imaging techniques. In short, Enzmann concluded, the new technique reveals differences between normal healthy organs and any abnormal structures in the body more easily and completely than any other single imaging method.

Even more information is available through magnetic resonance spectroscopy, which provides physicians with information about the continuous chemical and physical processes of the body, Enzmann explained. Instead of pictures, graphs of jagged lines can be interpreted to explain precisely what happens to the metabolic substance in question. This type of information, never available before, is enabling physicians to look at the body and disease in a brand new way, he said.

For example, with spectroscopy scientists can assess organs' acidity, known to increase when the supply of oxygen, carried by the blood, is reduced. By measuring the acidity, physicians can tell if a patient's blood is flowing through the body normally and exactly how well each organ is functioning.

With phosphate, it's possible to measure the level of energy concentrations in the body's organs. Again, this reveals how well the organs are functioning. Stanford's cardiovascular surgery department has already used this information to improve its transplant program.

"Even more exciting is the prospect of imaging spectroscopy where this important chemical information is displayed as an image rather than as a line," Enzmann said. "This would allow better understanding of the organ and disease process as a whole."

NEW BOOK INCLUDES MODEL OF THE HEART

STANFORD—

A new book designed to teach physicians and others about how to look at arteriograms and interpret them has been published by a widely recognized Stanford specialist and teacher of the subject.

Coronary Angiography: An Introduction to Interpretation and Technique, by Dr. James F. Silverman (126 pages, Addison-Wesley Publishing Company, Menlo Park, $19.95), comes complete with a plastic model of the heart, representing a simple way to interpret distribution of the various vessels.

The model can be put together almost like a doll cutout, giving a very rough approximation of the heart with the major vessels drawn in their common positions.

Stanford cardiologist Donald Harrison, who wrote the introduction, explains the model permits the student to visualize vessel motion in three dimensions instead of the two-dimensional mode in which vessels are normally viewed on a movie projector.

"It enhances understanding of angled views needed for optimal vessel evaluation," he adds.

Coronary angiography is an X-ray examination of the heart by means of introducing a thin plastic tube (catheter) into the left and right coronary arteries and following the course of an opaque fluid which has been injected into the bloodstream.

A high speed 35-millimeter movie will show the coronary arteries clearly, and study of the films in slow motion enables doctors to evaluate the condition of the heart.

Dr. Lewis Wexler, a colleague of Silverman and co-director of the Cardiac Catheterization Laboratory at Stanford University Hospital, calls the book "simple, straightforward . . . and written in a style that recognizes the needs of the novice, but with sufficient subtlety to benefit the experienced angiographer and residents and fellows preparing for board examinations."

Silverman, an associate profesor of clinical radiology and associate dean for clinical affairs at the School of Medicine, serves also as chief of staff at Stanford University Hospital.

"Heart disease is the number one killer in the United States, and coronary artery disease is the major perpetrator," said Silverman in explaining why he wrote the book. "Anyone caring for cardiovascular patients will be involved with coronary artery disease, and inherent in that situation is the need to understand vascular studies necessary for diagnoses."

SCIENTISTS UNRAVEL MYSTERIES OF SLEEP

Editors: This story first appeared in the *Stanford Medicine* magazine, winter 1985 issue. Photos and the magazine are available on request.

STANFORD—

Stanford University's 13-year-old Sleep Disorders Center has been writing the book on sleep disturbances from A to Zzzz!

But it has not been easy.

The possible causes—both medical and psychiatric—that come to mind upon hearing a person complain, "I can't sleep," constitute a veritable encyclopedia, says Dr. William Dement, director of the center. For many patients with insomnia or other sleep disorders, treatment is just not simple.

Researchers still don't know why people need sleep, Dement says, but they know we can't live without it. Sleep is as basic as food and water. People who have problems with it are apt to feel downright miserable.

James Dagdigian, a former patient, wakes up these mornings "bright-eyed and bushy-tailed," but it wasn't always so. Although he didn't realize it for many years, Dagdigian suffered from a sleep disorder that deprived him of sleeping well by night and functioning well by day.

Dagdigian's wife started wearing earplugs at night as soon as they married. Loud snoring wasn't his only problem. Dagdigian's professional and private life during his long navy career as a jet pilot was colored by chronic exhaustion, morning headaches and marred social relations. Then in 1977 his wife read an article about sleep disorders and Dagdigian came to Stanford for help.

Physicians diagnosed sleep apnea, a condition in which patients stop breathing for periods of about 30 seconds or more several hundred times a night and must awaken themselves to resume breathing, though they often don't remember doing so. The condition may occur when the brain's respiratory center, which regulates breathing impulses, malfunctions. It can also be triggered by muscle weakness that causes the upper airway to collapse. This prevents oxygen from reaching the lungs, explains Dr. Christian Guilleminault of the sleep center.

Dagdigian complained of daytime sleepiness, typical of about 60 percent of sleep center patients. Most of these are diagnosed as having sleep apnea. He underwent many tests, including 24-hour monitoring of physiological activity to identify sleep problems as they occurred. The process of diagnosis and treatment is tailored to each individual, Dement says, and is becoming increasingly complex. It's not unusual for a person to have more than one sleep disorder.

Factors to consider in each case include anatomical features, medications, weight, and other illnesses. All of these must be considered when deciding how severe the patient's condition is, what the appropriate treatment is, whether that treatment works or if something else should be tried.

-more-

2/21/85

Weight reduction—to relieve pressure placed on the airways by fatty tissue—may be all that's needed for some apnea patients. For others, a new treatment called continuous positive airway pressure is proving helpful, says Dr. German Nino-Murcia, a psychiatrist who runs the sleep clinic. A device supplying air at a certain pressure to the upper airway is used to provide the treatment to the sleeping patient. Several other treatments are available as well.

Unlike less severe apnea patients, Dagdigian needed surgery. A surgeon made a small hole in his windpipe below the voice box in his neck, which allowed oxygen to bypass the obstructed airway and pass into his system while asleep. He protects the opening, called a tracheostomy, with an implanted valve that he can open at night and close during the day.

As many as 50 percent of Americans over 60 years old may have serious sleep apnea whether they know it or not, says psychologist Dr. Donald Bliwise. Intellectual impairment in aging, he found, may reflect sleep apnea as well as more widely recognized ailments such as Alzheimer's Disease.

Sleep apnea probably contributes to the progression of heart disease—particularly arrhythmias—Dement says, and also may account for many "peaceful" deaths due to heart attacks at night.

"I was just cruising along as an accident waiting to happen," says Dagdigian, now 52. His father—who had many of the same symptoms—died at 51 of a massive heart attack, he recalls. Dement confirms that sleep disorders are increasingly found to run in families.

Established in 1972 as the first of its kind in the world, Stanford's sleep center offers the nation's only sleep disorders training program. In a young field tremendously in flux, Stanford clinicians and researchers are taking the lead to develop new and sometimes controversial treatments.

"Until about 1970 there was no notion of sleep disorders medicine," notes Dement, who is also president of the Association of Sleep Disorders Centers. "We're a sleep deprived society, yet only the waking patient had attracted medical attention." It's only by evaluating patients during sleep that doctors can pinpoint all the various factors underlying sleep disturbances, he adds.

Stanford's sleep center divides its efforts among pharmacological studies, animal studies, clinical research, and patient care. Besides sleep apnea, insomnia, and narcolepsy—the most common disorders encountered—physicians diagnose others such as sleep walking, sleep talking, infant apnea, periodic leg movements and impotence.

Having bred the world's only colony of narcoleptic dogs that mimic the human condition, Stanford sleep researchers are attempting to uncover the neurochemical imbalances involved in narcolepsy as well as solid clues to normal sleep mechanisms: what puts us to sleep, why we stay asleep, and what the sleeping brain does to allow us to be alert in the daytime.

Afflicting about 250,000 Americans, narcolepsy causes irresistible sleep attacks in its victims. The disorder is characterized by excessive daytime sleepiness, abrupt attacks of muscular weakness called cataplexy, hallucinations, and sudden attacks of rapid eye movement (REM) sleep.

"A person with narcolepsy who has slept through the night is still as sleepy during the day as you would be if I kept you awake for 48 hours," Dement says.

Until researchers find causes and a cure, only the symptoms of the disorder can be treated. According to Dement, the available drugs have their limitations.

Marilyn Wilder, a 59-year-old divorced mother of three who has had the disorder since the age of 15, knows just how important support from family and friends is. She makes herself available to fellow narcolepsy patients in need of a sympathetic ear. "I've talked to people on the edge of suicide," she says.

-more-

Education about narcolepsy is crucial for those in positions to offer employment or grant public assistance, adds therapist Sandra Foster-Rawlings. Obtaining adequate medical insurance coverage for all sleep disorders patients is yet another hurdle Dement's team hopes to jump.

Meanwhile, to help pry apart enigmas of the sleeping brain and to reduce costs, sleep center researchers are collaborating with engineers to develop home monitors that will enable patients to record their sleep at home. They are also devising new types of inexpensive tests for use at the clinic.

Home monitors are already used as life-savers for a category of patients considered at high risk during sleep, "near-miss" babies with infant apnea. These babies, like Jeremy Carney, may stop breathing in their sleep. Often already blue in the face, they are awakened by their parents and brought in for treatment.

"We don't know if these babies would die or eventually arouse themselves," Guilleminault says. A number of infants do die each year of sudden infant death syndrome (SIDS), but no one yet knows why. A higher incidence in certain countries and ethnic groups indicates the probability that socioeconomic factors, prenatal health care and nutrition play a role, he explains.

Jeremy's older brother suffered similar attacks during his sleep when he was an infant, "but the doctors just thought I was being overprotective," says their mother. Thanks to the medical establishment's growing awareness of the syndrome, Jeremy is being carefully watched and the Carneys can finally relax.

Increasing awareness about many sleep disorders has allowed Stanford's sleep programs to expand, Dement gladly reports. This winter the center is acquiring additional space at the Hoover Pavilion just down the road from the medical center. The new facility will include a comprehensive treatment program for insomnia.

Insomnia is treated through psychotherapy, behavioral techniques such as better sleep hygiene, relaxation and biofeedback. A promising new method called sleep restriction therapy, in which sleep is consolidated—first reduced, then slowly increased—into specific time schedules under a therapist's supervision, is also gaining popularity.

Some patients have trouble sleeping because their sleep-wake cycle is out of sync with normal body clock rhythms, Dement says. These patients may complain of not falling asleep until 4 in the morning though they have to get up at 7.

An innovative approach to combat this problem literally rewinds the body clock. Called chronotherapy, it requires patients to go to sleep a few hours later each day until they reach the desired bedtime.

A discrepancy often exists between what a patient really perceives and actually does, Dement says. "Based on evidence from patients, the odds are about 50-50 that you have insomnia if you think you do. Our first job is to find out if you do."

Sleeping pills, though highly effective for treating certain short-term forms of insomnia, Dement says, can cause or exacerbate sleep problems and lead to tolerance if used inappropriately. This is especially true for the elderly. Sleeping pills can be dangerous in sleep apnea patients because they interfere with their ability to resume breathing. "Most of these medications are respiratory depressants and may even induce sleep apnea," Dement says.

There is appropriate movement, he explains, toward a judicious, rational use of sleeping pills prescribed by trained professionals for certain cases of short-term or transient insomnia.

-more-

For most people, how much sleep is enough? The number of hours varies, Guilleminault says, but most normal adults feel they need between seven and eight hours of sleep to function well. "The main thing to look for is whether or not a person is complaining. A sleep complaint of any type is a good indicator that something is wrong. If you feel fine, then you probably have what your body requires," he explains.

Away from the main center near Lake Lagunita at the "Stanford Sleep Camp," researchers look into the special sleep problems of teenagers and other groups. The summer camp is staffed by Stanford students under the tutelage of Dr. Mary Carskadon, who has conducted studies on why teens seem to get sleepy so often.

Sleepiness, while not always felt or reported, can be measured with the multiple sleep latency test developed at the center. The test measures how fast a person falls asleep. "We consider five minutes or less the twilight zone," Dement says.

With the same amount of sleep, pre-pubertal volunteers were alert during the day, while those past puberty were sleepy, Carskadon found. This leads researchers to believe that as they grow older children need more, not fewer, hours of sleep.

Carskadon is looking at hormonal changes as well as circadian rhythms—the regular ups and downs of heart rate, brain waves, core body temperature and other rhythms of the body clock—to see if changes in these patterns during adolescence might cause increased sleepiness.

Meanwhile, societal pressures and possibly physiological changes lead teenagers to stay up relatively late. "Imagine the implications for school performance alone," Dement exclaims.

Stanford sleep researchers are looking into other challenging questions as well, such as what the sleeping brain does, what chemical changes underly the daily alternation of sleep and wakefulness, why some insomniacs don't feel sleepy during the day while others do, the effects of short-acting sleeping pills on jet lag and similar disruptions, solutions to the adverse effects of work shift rotation, and why some people experience long heart beat lapses during sleep.

"The riddles yet to be answered are as compelling as the breakthroughs," Dement says.

STANFORD RESEARCHERS SEEK NEW WAYS TO MINIMIZE EFFECTS OF ALZHEIMER'S DISEASE

STANFORD—

Anticipating a doubling in the number of Alzheimer's disease patients by the end of this century, a new research program is seeking to improve the quality of life for patients and help relatives better cope with caring for them.

The research program, which has received $150,000 funding for its first two years, differs from many other assaults against Alzheimer's by focusing on ways to minimize the psychosocial impact of the disease rather than on finding an underlying biological cause and a cure for it.

The Alzheimer's disease research is part of a clinical research center for the study of senile dementia, headed by Stanford University Medical School researchers and based at the Palo Alto Veterans Administration Medical Center. The center is funded by the National Institute of Mental Health.

"We're in the dark about what causes Alzheimer's disease," said Dr. Jerome Yesavage, Stanford assistant professor of psychiatry who heads the project. "The only thing we know for sure is that the disease will be with us in large quantities for the next 20 to 30 years."

For that reason, Yesavage said, it is important to ease the problems that often aggravate the disease and make coping more difficult both for patients and caregivers.

"We feel that we can minimize many of the medical, psychological and social complications of Alzheimer's even though a biological basis for the disease has not yet been discovered," Yesavage said.

He stressed that an additional goal of the research program is to encourage a variety of medical researchers to study problems of aging. "There are scientists with backgrounds in biochemistry and pathology who might have a lot to contribute to the study of Alzheimer's disease," he said.

More than 20 percent of the over-75 population is afflicted with Alzheimer's and related disorders, and the number of elderly people at high risk is expected to double by the year 2000, Yesavage said.

The increase is due to the growing numbers of the "old old," those over 75, who are most likely to be afflicted with Alzheimer's or similar forms of senile dementia that cause a gradual loss of intellectual functions and a variety of physical problems, Yesavage said.

In addition to the incalculable emotional costs for Alzheimer's patients and those close to them, the disease is a tremendous economic drain to the individuals involved as well as to society, he added.

"Each patient lives for an average of six to eight years after diagnosis with an annual medical and nursing cost of approximately $20,000 to $25,000," Yesavage estimated.

Common difficulties associated with Alzheimer's disease include memory loss, incontinence, movement disorders, as well as depression and sleep disturbances both in patients and in family or friends caring for a patient.

Many of these "excess disabilities" are treatable, Yesavage believes.

For example, Alzheimer's patients often have disrupted sleep patterns so that they can't go to sleep at night, but instead doze through the day. "It is quite likely that this is something we can learn to control pharmacologically or behaviorally," Yesavage suggested. "We may not need to understand exactly why a sleep problem arises before we can treat it," he said.

Sleep researchers Christian Guilleminault, Donald Bliwise, and Vincent Zarcone are among those involved in investigating Alzheimer's-related sleep disturbances, Yesavage noted.

Researchers will also try to determine what causes incontinence and whether it is preventable or treatable. Although it is not clear why some Alzheimer's patients lose control of urinary and bowel functions, incontinence is a major Alzheimer's-related problem and the most likely complication to cause depression in a caregiver, Yesavage said.

Drs. Carol Winograd and Inder Perkash will be pursuing possible treatments for incontinence, he added.

Biochemical changes in spinal fluid will be examined in an effort to find markers that might predict who is at risk for developing Alzheimer's disease and for distinguishing the disease from other syndromes such as severe depression, Yesavage said. Biochemical studies could also lead to clues about causes and possible treatments for the disease, he added.

Among those looking at the biochemistry of Alzheimer's patients are professors Jack Barchas, Philip Berger, and Larry Eng, Yesavage said.

Ways of reducing or coping with depression in caregivers is another phase of the study that will benefit not only the caregiver but the patient as well, Yesavage said. If the caregiver becomes depressed enough, then the patient may suffer too, from lack of care, Yesavage explained.

Electrophysiological measurements of brain activity and computerized brain scan techniques will also be explored by Dr. Adolf Pfefferbaum, as diagnostic tools to spot early signs of dementia, Yesavage said.

"We're working from the premise that this disease will become increasingly common in the next few decades," Yesavage said. "The question is, how are we going to deal with it and how are families and caretakers of Alzheimer's patients going to get maximum benefit for the patient from the fixed resources available? The answer is that we have to find and concentrate on the aspects of the disease that are remediable," he added.

Some other institutions with major research centers for the study of Alzheimer's disease are the University of California, San Diego, the University of Southern California, and the Bronx Veterans Administration Hospital, he said.

DIABETES STUDIES NEED VOLUNTEERS

STANFORD—

Volunteers are needed for two studies being conducted in Stanford Medical Center's clinical research center (CRC) under the direction of Dr. Gerald Reaven, professor of medicine.

One study will examine the link between diabetes mellitus and fat metabolism by comparing diabetics being treated with oral medications, or diet —but not insulin— to non-diabetics. The study will use standard meals and infusions of glucose and insulin, to assess responses in blood sugar, insulin, and fatty acid levels.

The other study will examine the link between diabetes mellitus and atherosclerosis (hardening of the arteries). It will analyze blood samples of non-diabetic people with a family history of diabetes— or a personal history of "borderline" diabetes —for glucose, insulin, and cholesterol levels.

Volunteers for both studies must be between 40 and 75 years old and able to spend two to three mornings in the CRC.

Participants will receive a free physical examination, including a glucose tolerance test, and dietary consultation.

For more information call Dr. Arthur Swislocki, between 9 a.m. and 5 p.m., at (415) 497-6973.

STUDY NEEDS MALE VOLUNTEERS

STANFORD—

Male volunteers 21-30 years old, or above the age of 70, are needed to participate in a study comparing the relationship between hormones and sexual functioning in the two age groups.

Volunteers should be in good physical and mental health. They will be asked to contribute two to six hours of their time. The results of all laboratory tests, procedures, and analyses will be made available to them at the end of their participation, said Dr. Julian Davidson, professor of physiology, who is conducting the study with associates as part of a larger, ongoing research effort.

Tests include monitoring sexual arousal under various conditions, and taking blood tests to determine hormone levels.

For further information call Dr. David Rowland, at (415) 497-2432, between 9 a.m. and 5 p.m.

FEDERAL JUDGE DISMISSES LAWSUIT INVOLVING VA DOG

STANFORD—

A federal judge has dismissed a lawsuit stemming from the removal and subsequent death of a research dog from the Palo Alto Veteran's Administration Medical Center (PAVAMC).

Stanford University had been named as one of five defendants in the suit dismissed Feb. 5 by U.S. District Court Judge Stanley Weigel. Three humane societies brought suit April 12, 1984, asking the court to stop all research involving dogs and cats until federal regulations for research animals were met to the satisfaction of the plaintiffs.

A VA panel concluded in May 1983 that while no violations had occurred, several changes in cage design—since adopted—could help ensure that accidents would not occur in the future.

The dog, which was part of a study intended to perfect techniques for repairing and replacing blood vessels, was taken from the VA late at night on March 24, 1983, nine days after surgery, by a medical student.

The veterinarian responsible for the dog's care said the student refused her request that the dog be returned to the hospital for treatment.

The animal subsequently was put to death by a Palo Alto veterinarian who told a news conference called by the Santa Clara Valley Humane Society that he believed the dog was suffering and could not recover.

The VA panel concluded that the dog, while still anesthesized after surgery, had been bitten several times by a dog in an adjacent cage. Since the incident, the VA has installed special postsurgical recovery cages and has posted emergency phone numbers of personnel in animal areas.

Humane society spokesmen have been critical of the VA panel's report, but a followup investigation by the United States Department of Agriculture (USDA) found the incident was isolated and that the subsequent changes by the VA corrected the situation, said Rodney Johnson, managing attorney for medical affairs.

"We are gratified that the court has clarified a potential misconception about Stanford's standards of animal care," said David Mendelow, associate dean for administration at Stanford Medical Center.

"The case never did involve the issues of animal care at Stanford, and we now feel vindicated because the continuing efforts to provide both quality research and quality care can continue without the confusion in the public mind that this suit has brought."

-more-

2/13/85

"We're disappointed, but that's the way things go," said Warren Brodrick, executive director of the Humane Society of Santa Clara Valley, a plaintiff.

Weigel's brief dismissal order said the court "has concluded that plaintiffs lack standing to prosecute this action, and further that, in any case, the matter is moot, and that plaintiffs have failed to state a claim upon which relief can be granted." Besides Brodrick's group, plaintiffs included the San Mateo-based Peninsula Humane Society and the Palo Alto Humane Society.

Defendants, in addition to Stanford, were national VA Administrator Harry N. Walters; James DeNiro, director of the PAVAMC; the secretary of agriculture; and Dr. Craig Miller, associate professor of cardiovascular surgery at Stanford, who was conducting VA-sponsored research involving the dog.

Johnson said the university should not have been included in the first place, since all research involving the dog had occurred at the VA. Stanford had asked the judge to drop the university from the suit if it had continued.

Dr. Malcolm Anderson, assistant professor of radiology at Stanford and assistant chief of radiology at the VA, headed the VA panel which criticized the student "for delaying treatment of the dog by several hours" by removing it.

Brodrick called that report "a massive whitewash by the committee (VA panel)." He said that his attorneys have received copies of the USDA's followup report but that he has not read it and cannot comment on the document.

Both Mendelow and Brodrick, in separate interviews, agreed that the legislature, not a court of law, was the appropriate place to make rules involving the care of animals.

"Our elected lawmakers are the appropriate persons to provide the underlying guidelines to balance the needs of lifesaving research with the very genuine concern for the humane care of laboratory animals," said Mendelow. "Litigation is not the appropriate forum for policy. The case of an individual research dog was investigated with appropriate action taken by our Veterans Administration colleagues."

Brodrick said the current case "does point out that there probably is a need for a change in the state law" which currently exempts research animals from the cruelty provisions of the law.

Currently, USDA regulations, not state law, govern the standards of care for research animals.

PHYSICIAN SAYS MEDICAL CUTBACKS HURT FUTURE DOCTORS

STANFORD—

Federal cutbacks for health care would affect not only low income patients, but would also interfere with Stanford's ability to train future doctors from all income backgrounds, a faculty physician testified Wednesday (Feb. 13).

"The President's 1986 budget request proposes cutbacks in expenditures which will adversely affect the ability of Stanford University Hospital and Medical School to provide health care services to the poor, aged and chronically ill, and to fulfill its goal of training physicians from all levels of society to become the future leaders in medicine," said Dr. Lewis Wexler, a cardiac radiologist.

Wexler's statement was prepared for delivery in testimony Wednesday at a public budget hearing held in Millbrae by Rep. Tom Lantos, D-Calif.

Medical students from low and lower-middle income families "would be disporportionately affected" by proposed cuts in federally supported loan programs, Wexler said, adding about 75 percent of Stanford's 400 medical students currently participate in federal loan programs. In 1984, the average medical student had a debt of $28,000, he said.

"The proposed ceiling of $4,000 per year in support from all federal sources would create an average unmet need of $2,500 per year, and for our neediest students, their unment financial burden would be closer to $6,500 per year," Wexler said.

"Significantly, our ability to attract students of low income families will be impaired which may seriously affect our affirmative action minority recruitment efforts," Wexler said.

He predicted in 1985, Stanford University Hospital would be required to forgo $3.5 million in medical education payments, a reimbursement provided to university hospitals in recognition of their higher costs.

The administration has proposed cutting this indirect medical education payment provided teaching hospitals from 11.59 percent to 5.79 percent of payments.

"This payment (indirect education costs) is predicated on the fact that sicker patients are referred for treatment in teaching hospitals and that there is an added cost incurred in educating young physicians, for example, for classrooms, teaching materials, added time and personnel," Wexler said in remarks prepared for delivery.

SUH statistics show that 33.2 percent of the institution's patients are Medicare supported, while 11.8 percent are Medi-Cal. The hospital admits approximately 23,000 patients annually.

In an earlier statement, Arthur Kornberg, a Nobel Prize winning Stanford biochemist, called proposed cuts for medical research "a very calamitous decision.

"The cuts would not only destroy a large segment of our scieintific talent, but they would send a message to our younger scientists that they cannot be assured of support even if they have done distinguished work and spent years in specialized training," Kornberg said.

The Reagan administration has proposed reducing the number of National Institutes of Health grants by 23 per cent, from 6,500 last year to 5,000. Administration officials have said the cuts will save $280 million from the $5.1 already appropriated by Congress for the NIH this year.

NEW COMMITTEE LOOKS AT ETHICAL ISSUES OF LIFE, DEATH AND MEDICAL CARE

STANFORD—

Patients and physicians at Stanford University Medical Center now have a resource when they have questions about making life and death decisions and other ethical issues—a special ethics committee.

Withdrawing life support, 'do not resuscitate' codes, informed consent, animals in research, severely impaired newborns and economics are just some of the issues being analyzed by the medical center's committee, which includes physicians from all specialties, nurses, medical students, chaplains, economists, lawyers, social workers, sociologists and philosophers.

The emergence of ethics committees has been necessitated by a technological revolution in medicine, forcing physicians and patients to face issues, such as cost and quality of life, that never before have been considered.

Patients and community members can now get legally binding documents in which individuals can express whether or not they desire extraordinary life support systems withdrawn or withheld in the event of terminal illness at Stanford. These documents include a Living Will, a California Natural Death Act Directive and a form to assign a Durable Power of Attorney for Health Care in California. They are available in Stanford University Hospital's community relations office (415-497-7167). The information has also been included in the revised patient information brochure distributed to all patients admitted to the hospital.

"We have established ourselves as a resource for the entire community for these documents," said Dr. Thomas Raffin, assistant chief of medicine and committee member.

The committee has developed an eight-hour long ethics section to be incorporated beginning this spring in a basic clinical medicine course that all medical students are required to take before they begin seeing patients.

The committee has started sending a series of mailings in which they will advise all physicians, nursing and patient support staff at Stanford University Hospital of the various issues in question and alternatives to dealing with them.

"We are more than willing to look at individual cases retrospectively," Raffin said.

The hospital has also established an ethics committee that physicians and health care personnel can seek out for advice on ongoing cases.

The center-wide committee was established in September 1983 by vice president for medical affairs Dr. Lawrence Crowley.

Chaired by Dr. Thomas Gonda, who heads the psychiatry and behavioral sciences department, the committee was charged with helping to identify the medical center's ethical issues; broadening the awareness and understanding of these issues; suggesting policies and practices aimed to assure sound decision-making in ethically difficult situations and helping to develop ethics courses to add to the center's educational programs.

THE HEALING POWER OF LASERS

STANFORD—

Mention laser and people conjure up images of Luke Skywalker zapping Darth Vader in *Star Wars*. Mention laser to physicians, and the word takes on new meaning. Since scientists began harnessing this unique form of light energy for medical use, lasers have been heralded as miraculous by physicians who jumped on the laser bandwagon. Today, more than 20 years later, enthusiasm for lasers has not significantly diminished. But physicians now realize that treatment with lasers must be thoroughly studied and tested in order to get the greatest therapeutic value from these weapons against disease.

"Lasers have found a niche in medicine. More and more specialties are using them for routine procedures," says Dr. David Apfelberg, a medical staff member at Stanford University Hospital and director of Palo Alto Medical Foundation's laser center.

"A lot of the initial flurry has been because lasers are the new kids on the block," adds Dr. Robert Ginsburg, Stanford cardiologist. "Everybody has been using them, but they haven't yet done anything that cannot be done with other available technology."

But that doesn't mean Ginsburg and other physicians aren't interested. "We're pursuing lasers because the physics is so complex and so interesting that lurking in all the light wavelengths has got to be the right one that will do what everyone has envisioned lasers will do. With enough research, we'll find the answers."

A laser, the acronym for Light Amplification by Stimulated Emission of Radiation, involves either a gas, liquid or solid. The gas laser—the most commonly used in medicine at this point—is basically a glass tube with mirrors at each end. The tube emits coherent precisely directed, powerful beams of light consisting of one or more colors. In contrast, ordinary light spreads its energy in a halo shape and consists of a diffuse spectrum of colors. The type of gas or other substance in the laser tube determines the color emitted, which determines what what type of tissue will absorb the light as well as how penetrating that light will be. Depending on the type of laser, the beam either vaporizes the tissue with heat or explodes it with concentrated energy.

"Lasers have really turned the tide for many patients who would have gone blind in the past," says Dr. Michael Gaynon, a retina specialist in Stanford's ophthalmology department.

Ophthalmologists, he continues, are one group of physicians who are convinced of the superiority of lasers in treating a number of eye diseases.

Many diabetics develop eye diseases that cause either hemorrhage or detachment of the retina, the light-sensitive tissue lining the back of the eye. Even those diabetics who are not as severely affected often develop leakage from abnormal capillaries, sometimes suffering severe loss of vision. By using the argon laser, which emits a blue-green beam of light, ophthalmologists can cauterize the leaky vessels or weld the retina back onto the eye. At the very least, Gaynon says, this often allows them to stabilize their patients' vision; sometimes they can even improve it.

The elderly often lose reading vision because of little blood vessels that grow abnormally and bleed underneath the retina. The laser can cauterize these errant vessels and preserve patients' vision. And in patients who have retinal tears—about two out of every 100 among those who have had cataracts removed—the laser can weld the tear to keep the retina from detaching.

Ophthalmologists are using lasers more and more to treat glaucoma. This is a disease that can cause blindness, especially in people over 40 years old. The condition is caused by blockage of normal fluid seepage out of the eye, which prompts the pressure to increase until it damages the entire eye. By using lasers, physicians "irrigate" the eye by making minuscule holes in the iris. This irrigation restores the pressure back to the normal range. Until now, this could only be done surgically.

Another type of laser, called the neodymium YAG laser, emits an invisible infrared light. It creates microexplosions that literally blow up the tissue, Gaynon explains. Though still considered experimental by the Food and Drug Administration, the YAG laser is now used along with surgery on many of the 500,000 cataracts removed each year.

Gaynon is especially excited by his department's acquisition of a rare type of laser called the yellow Krypton laser. One of only about four in the world, he says, the yellow Krypton was purchased along with other lasers with a gift from the Televideo Corporation, Sunnyvale. Unlike the blue-green light produced by the argon laser, which is more easily absorbed by the central reading portion of the retina, the red and yellow light produced by the yellow Krypton laser is not, Gaynon explains. Thus, because of less chance of damaging healthy tissue, it may be preferable, he says, to use alone or with the argon laser when treating a section of the retina called the *macula lutea*, which is responsible for sharp focusing.

"The yellow Krypton laser will set us apart from other laser centers," Gaynon predicts.

It was two Stanford ophthalmologists who used one of the first crude lasers made with a red ruby crystal to treat a patient. The laser's development came just four years after Stanford physicist and Nobel laureate Dr. Arthur Schawlow and his brother-in-law, Berkeley physicist and Nobel laureate Dr. Charles Townes, conceived of the idea for a monochromatic and extremely intense beam of light. The ophthalmologists, Drs. Christian Zweng and Milton Flocks, treated their first patient in 1963, spot welding his retina back onto his eye.

"Everyone knew the laser was great, but nobody knew what to use it for," Flocks recalls. "We had seen it used for nonmedical purposes, and realized it would work for our needs as well."

Further exploration of lasers, and development of the argon laser was carried out at Stanford Research Institute by scientists including Zweng, Flocks, and Dr. Hunter Little.

Laser light beams are produced when an external energy source stimulates the atoms of the gas inside the glass tube. This causes the atoms to release photons, tiny packets of light. A mirror at one end of the tube reflects the photons, while a mirror at the other end is specially made to allow some of the light packets to escape in form of a beam. As the photons speed back and forth between the two mirrors they create a chain reaction that makes a powerful beam of focused, one-color light.

-more-

Ophthalmologists may have been the first to use lasers as a treatment, but they weren't alone for long. "Two years ago you couldn't have found a podiatrist with a laser. Now they're all using them," Apfelberg says. "Every modern neurosurgeon is trained with lasers, whereas 10 years ago, no way. They're used in plastic surgery, otolaryngology (ear, nose and throat), gastroenterology and urology, just to name a few areas. Five years ago you could hardly find any obstetrics and gynecology doctgrs using lasers. Now it's very common."

The laser beam is so precise it doesn't destroy surrounding tissue, explains Dr. Olive Soriero, an assistant professor in the gynecologic oncology section of Stanford's gynecology and obstetrics department. It's less invasive than other techniques and it's often more comfortable for the patients.

"We use lasers for benign conditions, such as warts, on the female genital tract," she says. "We also use them to eliminate abnormal cell areas to prevent the development of invasive cancer. Lasers are much easier and more effective when we use them together with a colpiscope, which magnifies areas in the vagina, cervix and on the vulva that in the past were harder to detect."

Soriero says the carbon dioxide laser is preferable in ob/gyn because it vaporizes surface tissue. The heat cauterizes the surrounding tissue to prevent most bleeding, and other than a little ash left on the surface, nothing remains. "It really is like *Star Wars*," she marvels.

Lasers are just now beginning to be used in surgery on the fallopian tubes to reverse infertility, she adds. With other types of treatment, healing time can be as long as 10 uncomfortable weeks or even longer. With lasers, Soriero says, healing time is as short as four weeks, with less scarring and discomfort to boot.

Lasers first became popular among dermatologists when they found the light beams could bleach port wine stains, unsightly purplish blotches that can cover large areas of the face. Composed of tiny blood vessels, the stains absorb the laser light and are destroyed. "These stains were never before treatable," Apfelberg says. "Even if you can lighten a stain 60 percent, and the person can just use regular makeup to camouflage it, you've made their quality of life that much better."

Dermatologists use lasers to treat warts, some moles, scar tissue and to remove tattoos. They cut down on scarring and are useful in surgery because the cauterizing effect creates an almost bloodless field, says Dr. Robert Roth, who teaches dermatology at Stanford and has a private practice in Fremont. But he's not sure these advantages are "real" yet. "Some people have said that in dermatology lasers are an instrument in search of a disease. Nobody knows if they're better," he notes.

It's true that just about everything lasers do can be done with another treatment, Apfelberg agrees. "But there are some conditions for which there just is no other treatment except lasers." And even for those conditions with other treatments available, he adds, "lasers are usually a gentler way of doing it."

This is not to say lasers are perfect, however. Apfelberg cautions that lasers can be dangerous to the user: they can start fires and the high voltage machines can even electrocute. The beam can harm unprotected eyes if reflected into them, and if it unintentionally hits someone's teeth, for example, it'll chip them. And, if the beam comes in contact with a gas in the patient's body—in the trachea, for example—it could blow it up. While these potential hazards need to be considered, Apfelberg says, research shows that laser energy, unlike some other forms of radiation, does not affect future cell generations.

And then there's the issue of cost. Lasers are expensive, starting at about $45,000 for an argon laser. To make them cost effective, they've got to be used and shared among departments as much as possible, Roth says. Yet Soriero feels that high cost may be one way of limiting use of the machines to those who are best trained.

-more-

"It's just as well that not everyone can afford to buy one because not everyone should be using lasers," she explains. "Lasers are not machines every doctor's office should have. They should be used by doctors who are specially trained and who use them a lot, as would doctors in a laser center. If it's a choice of a doctor having one and not knowing how to use it well, and not having one at all, the latter is preferable."

Yet for physicians who do have access to lasers, the intrigue to press on to discover their full potential is there. Cardiologist Ginsburg made medical history in 1983 when he used a laser to vaporize atherosclerotic plaque from the arteries in a patient's leg. Lasers have also been used in cardiology to create openings in babies born without the proper vascular connections and to eliminate abnormal tissue thickenings that interfere with performance. Although Ginsburg still uses lasers for these procedures, he's back in his laboratory.

"We took a backward approach," Ginsburg explains. "We went straight to the clinical end, investigated one small area of this interesting form of energy, focused in on it, learned a lot about it, and now we're going back into the lab. We're studying the effects of lasers and trying to find the proper wavelength to enhance the ability of the laser to do everything we want it to do."

Ultraviolet lasers seem to be the most promising for use in cardiology, Ginsburg feels, because they damage the tissue less than other types of lasers. They initiate a photochemical process that helps destroy tissue. "The ultraviolet laser would break up the tissue rather than boil it," he explains.

Ginsburg is also investigating how to get the laser energy to the plaque area in the least invasive, most efficient way. "Working out the mechanics of using lasers to get rid of atherosclerotic plaque is one thing," he says. "Understanding the biology of plaque to make lasers better than techniques currently available is another challenge altogether."

What would enhance the laser, he says, would be to find the right chemicals to inject in the atherosclerotic plaque to make it more sensitive to laser light than normal tissue. He knows it's possible, because this technique is being used in other areas, such as cancer treatment.

Twelve centers in the United States currently have the protocol to use a tunable dye laser and a chemical, hematoporphryn derivative (HPD), to kill cancerous cells. Apfelberg hopes his laser center at the Palo Alto Medical Foundation will be the next to receive the protocol. Physicians inject HPD, which is selectively absorbed by cancerous cells but not healthy cells. The laser light can then destroy the HPD-enhanced cancer cells; the healthy cells remain unharmed. Preliminary results show this method to be successful in combating bladder, lung, and skin cancer.

"It's not a miracle and it's not a cure-all," Apfelberg is quick to point out. However, he adds, used with other treatments such as radiation and chemotherapy, it could help overcome some common cancers.

"The answers are out there," Ginsburg says. "It's just a matter of getting enough support and working hard enough and long enough to find them. If we can find the answers, then yes, lasers will be better than many treatments we have available now."

CORPORATION EXECUTIVES TOLD OF HOSPITAL MODERNIZATION BENEFITS

STANFORD—

How to fit modern, high quality patient care into the physical and financial confines imposed by buildings that lag behind the times is the fundamental problem that plagues not only Stanford University Hospital, but most other U.S. hospitals, Peninsula corporation executives were told last week.

Technological advances have long outpaced the building's capacity to provide care efficiently, said Sheldon King, executive vice president and hospital director.

King spoke at two fund-raising breakfast meetings held Thursday and Friday at the Saga Corporation and attended by 25 executives of Peninsula corporations.

These and other deficiencies will be corrected when the two-phase $112 million hospital modernization project under way is completed in 1987, King said.

When intensive care units were being established in the early 1960s, he explained, Stanford hospital became an innovator.

But despite the architectural beauty of the buildings, one intensive care unit (ICU) had to be established along a straight corridor, instead of the more desirable circular pattern around a nursing station. As a result the ICU has to maintain a ratio of one nurse per patient--an inefficiency that adds to high costs.

Similar problems plague the outdated operating rooms. They are too small and two few to accomodate some of today's sophisticated surgery, and needs of the medical staff.

"It's often necessary for the hospital to schedule procedures late into the night," King said. "While this may appear to be an efficient use of operating rooms, it isn't desirable when the surgeons involved have been seeing patients all day."

Even storage space has been inadequate because of the mountains of disposables the hospital now uses. He said improvements made last year in materials management alone have resulted in $1 million savings.

The goal of the modernization, he explained, is not simply to correct code deficiencies for which the hospital was cited in the past, but to provide a modern environment to allow the hospital to carry out its missions of patient care, teaching and research, and to reduce operating costs.

2-8-85

-more-

The modernization includes construction of new operating rooms, modern intensive care units, consolidation of many clinical laboratories now scattered throughout the hospital and medical center, new isolation and recovery rooms, anesthesia space, facilities for magnetic resonance imaging, and a surgicenter for outpatient procedures.

The project will also permit the closing of Hoover Pavilion which poses inconvenience to patients, and is uneconomical to run because of the distance from the hospital.

Other speakers included Dr. Robert J. Glaser, director of medical science for the Markey Charitable Trust, Menlo Park, and heart transplant pioneer Dr. Norman E. Shumway.

Glaser, who co-chairs the governing committee for the overall fund-raising agenda of the medical center, said that some of 20th century's most important medical advances originated in the hospital.

"Because of the hospital and the medical school many outstanding physicians have been attracted to this area which enjoys some of the best medical care in the world," he said.

"The hospital is both a community and a national asset and it must be supported to continue making its contributions to the community and to society."

The meetings were organized by Richard G. Rogers, president and chief operating officer of Syntex Corporation of Palo Alto. He heads the hospital modernization fundraising effort, assisted by Albert Eisenstat, vice president and general counsel of Apple Computer, Cupertino; Jack Black, Central California vice president for Pacific Bell in San Jose; and James W. Morrell, executive vice president, Saga Corp., Menlo Park-based national food supplier.

The committee plans to raise a minimum of $1 million toward the project's $15 million goal.

Hewlett-Packard Co. (HP) has offered a $250,000 challenge grant to area corporations to support the hospital's modernization project which will be funded by a combination of gifts, bonds and hospital reserves.

John Young, HP president and Stanford trustee, said his company would contribute $1 for every $4 raised from other corporations.

Morrell announced at the meeting that his company, Saga Corporation, has pledged $100,000 toward the hospital project over a five-year period. Similar pledges have also been made by PG&E, Varian Associates and the Lane Publishing Company. Total contributions from corporations todate equal almost $500,000, not including HP's matching contribution.

King pointed out that 68.8 percent of the patients served by Stanford University Hospital come from Santa Clara County, the remaining from other parts of California and the west. A total of 33.2 percent are Medicare patients and 11.8 percent are Medi-Cal.

"From among some 400 teaching hospitals in the country, national polls have consistently rated Stanford hospital among the 10 best," King said.

"This has occured because of the work of outstanding individuals like Shumway," he added.

SCIENTISTS REPORT NEW FINDING ABOUT BLOOD DEVELOPMENT IN BABIES

STANFORD—

Blood composition in infants born to diabetic mothers is slightly different from that of babies of non-diabetic mothers, Stanford University and Harvard University scientists reported in the Feb. 7 issue of *The New England Journal of Medicine*.

The finding poses no danger to infants of diabetic mothers, the scientists stressed. The difference is in one portion of the oxygen-carrying protein, hemoglobin, and both forms of hemoglobin are effective in carrying oxygen through the bloodstream, the scientists said.

But the finding is of interest, they added, because it could provide new information about how hemoglobin genes are controlled during fetal development.

The study was conducted by Dr. Susan Perrine, assistant professor of pediatrics at Stanford University School of Medicine and Drs. Michael Greene and Douglas Faller of Harvard Medical School.

A similar finding was independently discovered by Dr. Harry Bard of the St. Justine Hospital in Montreal, Canada, Perrine said.

Normally, a baby developing in the womb produces one form of hemoglobin, known as the fetal form, until the last month or so before it is born, when it switches to the adult form of hemoglobin.

The switch occurs when a gene coding for one portion of the hemoglobin molecule is turned off and another gene is turned on. The genes code for protein subunits of which hemoglobin is made.

Fetal hemoglobin contains a protein subunit called the gamma chain, which in adult hemoglobin is replaced by a protein subunit called the beta chain.

The scientists found that in nine out of ten developing babies of diabetic mothers, the switch from fetal hemoglobin to adult hemoglobin did not occur. These infants continued to produce the gamma protein subunit rather than beta, and thus were still producing predominantly fetal hemoglobin at the time they were born.

This suggests that some factor present in developing babies of diabetic mothers can alter the normal gamma-to-beta gene switch process, Perrine said.

The scientists do not yet know what that factor might be. One guess is insulin, which these infants produce in higher than normal amounts in response to the high blood sugar levels of their diabetic mothers.

Recent reports by other researchers have indicated that insulin can affect the activation of genes, Perrine said, and further studies are under way to learn if insulin is responsible for keeping the gamma gene switched on.

Perrine stressed that it is too early to predict clinical implications at this stage in the research.

But it is important to continue studying how the genes coding for hemoglobin's constituent protein chains may be controlled during development, Perrine said, because some prevalent types of blood diseases arise from abnormalities in these chains.

The research was supported by grants from the National Institutes of Health, the Cooley's Anemia Foundation, the Charles H. Hood Foundation, the Anna Fuller Fund, and the American Cancer Society.

STANFORD HEART TRANSPLANT RECIPIENTS RATE LIFE SATISFACTION HIGH

STANFORD—

Life satisfaction is high among patients who have received heart transplants at Stanford University Medical Center despite some post-transplant difficulties, a new patient survey shows.

In a questionnaire completed by 75 heart transplant recipients, just under 90 percent reported that their quality of life was good to excellent and 82 percent said they were highly satisfied with their current quality of life.

It is the first study to examine heart transplant patients' own assessments of their post-transplant quality of life, said Mary Lough, a Stanford cardiovascular nurse educator who conducted the survey while earning her masters degree at the University of California, San Francisco.

She was to present a summary of the study's findings Friday, Feb. 8 at a closed symposium on cardiac transplantation sponsored by Stanford Medical School's division of cardiology and department of cardiovascular surgery, and by Stanford University Hospital's department of nursing.

Lough was also scheduled to appear at a news conference Wednesday, Feb. 6 associated with the symposium.

Lough said that the study was done because heart transplant operations are no longer considered experimental procedures but are becoming increasingly accepted as an important form of therapy for some patients with end stage heart disease.

The one-year survival rate for Stanford patients is now 83 percent, with 45 to 50 percent of patients surviving five years, according to the transplant program's statistics.

"This means that survival is no longer the only issue for heart transplant recipients," Lough said. "Quality of life has become important."

Lough said a striking finding was that most patients in the survey were highly satisfied with their lives following the transplant operation even though many reported some medical problems and financial difficulties following the operation.

"We cannot yet draw any conclusions about this finding," she noted, "except that a person's subjective feeling about quality of life can be good despite objective problems."

For example, Lough noted that most patients reported side effects from the anti-rejection drugs they must take on a continuing basis. The side effects ranged from minor symptoms such as tremors and bruises to major complications such as lymphoma, a cancer of the lymphatic system.

2-6-85

-more-

"Yet most patients considered the risk that they might contract major complications to be insignificant in determining current quality of life," Lough said.

The questionnaire focused on change experienced by the patients in the areas of family life, social life, work, vocational rehabilitation, emotional and physical well-being, and future outlook, Lough said.

The change experienced by the largest number of patients—32 percent—was in occupation, Lough said. If heart transplant recipients were employed they reported a higher quality of life and less financial strain than recipients who were homemakers, students, retired, or on medical disability. Employment, though, had no effect on life satisfaction, Lough said.

After transplantion most patients also reported a change for the better in health status, future outlook, relationships with children, feelings about self, social support and sense of achievement.

Change for the worse was reported by many patients in physical appearance and financial situation.

Yet more than 95 percent of those in the survey said that having gone through a heart transplant procedure and knowing what they now know, they would do it all over again, Lough reported.

Most patients reported little change in their family situations, including relationships with spouse and other relatives. For most, their family was the most important factor in contributing to a good quality of life, Lough added.

Lough mailed the questionnaires to 100 Stanford heart transplant patients. The group consisted of all surviving English-speaking recipients over the age of 18 who were at least six months post-transplant, she said.

Seventy-five answered the questionnaire, a very high response rate, Lough said.

Those responding ranged in age from 19 to 60, and in time since transplantation from seven months to 14 years, Lough said.

KORN APPOINTS TASK FORCES TO EXAMINE KEY MEDICAL PROGRAMS

STANFORD—

Three task forces to examine the scope and direction of new academic programs of the Stanford University School of Medicine have been appointed by Dean David Korn.

The groups will review and make recommendations to the dean about:

- expanded programs in organ transplantation medicine—specifically kidney and bone marrow.
- nuclear magnetic resonance (NMR), and
- primary care.

The task force recommendations will be important for the academic directions of the medical school, stressed Korn who assumed the deanship earlier this year. The new programs had been under development for some time.

Korn said he put the plans temporarily on hold, "because we now have the opportunity to determine whether they provide for optimum development of transplantation medicine, the future directions of NMR, and primary care at Stanford."

The task force on transplantation is co-chaired by Korn and Stanley Schrier, professor of medicine. David Prince, professor and department of neurology chairman, will head the committee on NMR, and Duncan Govan, professor of surgery, will chair the primary care task force.

A subcommittee of the latter group, headed by Halsted Holman, professor of medicine, will examine how the faculty medical practice should be organized to strengthen its regional role as a provider of medical services.

"The school has desired for some time to initiate clinical and research activity in kidney and bone marrow transplantation to complement the distinguished pioneer program in cardiac and heart-lung transplantation," Korn explained.

This, however, raises questions of academic emphasis, cost, space and staffing as well as impact on the various components of the medical center. The task force will examine:

5 Feb. 1985

-more-

- whether the new programs should include liver and other more experimental forms of transplantation, perhaps under the concept of a comprehensive center.
- the laboratory space and numbers of surgeons, and other specialists required, and
- the nature and extent of research and teaching efforts devoted to immunobiology, immunotherapy and fields related to transplantation medicine.

"I have asked the group," Korn said, "to be realistic with respect to available resources and be perceptive at the same time of future trends and opportunities in this field."

The NMR committee, Korn said, will examine the academic plan, review the rationale and recommend an appropriate governance for the proposed NMR Center.

Magnetic resonance provides physicians with a new diagnostic tool from which they can obtain anatomic and metabolic information. The medical school has been planning a center designed to enhance the uses of NMR in imaging, spectroscopy, and fundamental chemical and molecular biology research.

A separate magnetic resonance imaging (MRI) facility for patient diagnosis is planned by the hospital. Meanwhile, an MRI facility under the auspices of the Faculty Practice Plan will open shortly in rented space in Mountain View, where outpatients will go to have images taken.

The primary care task force will examine the advantages to the medical school of embarking on a program which would increase the type of medical care services provided by general physicians as opposed to specialists.

Such services are now provided by the Stanford Medical Group in the Stanford University Clinic.

Some faculty and administrators believe that enlarging primary care services would improve Stanford's position as a provider of comprehensive health services now demanded of medical institutions by insurance plans as well as business organizations for their employees.

"The move might also help the school retain its patient base for teaching and the highly specialized care which Stanford is uniquely able to offer," Korn said.

The task force will consider "how decisions to expand medical care programs and develop novel patterns and sources of patient referral might impact the organization of the medical school, the full-time and part-time faculty as well as community physician participation and interaction."

NEW ART SHOW FEATURE PHYSICIAN'S AND HIS GRANDCHILDREN'S WORKS

STANFORD—

A new show at the Stanford University Faculty Club features paintings of Dr. Joseph Kriss, Stanford University Medical Center professor—and those of his grandchildren.

Kriss, who directs Stanford's nuclear medicine division, has been painting since his college days and is an accomplished painter with many one-man shows to his credit.

But his grandchildren, two- and three-year-old Aaron and Jesse, have yet to learn how to write their names.

Yet they tried out some of his paints and brushes during their last visit, Kriss said, and taught him a thing or two about painting and creativity.

The paintings in the show, which opened Feb. 2 and is scheduled to run the entire month, are free-form and abstract. In many, the brightly colored swishes across the paper are pleasing to the viewer. Grandfather's and grandsons' paintings are undiscernible.

Kriss said he gave the boys "no direction, made no suggestions and asked no questions. I made a conscious choice to give them free rein in the studio. They could choose any medium, any color or combination of colors, any brush, any size and type of surface to work on.

"Both boys painted with complete assurance, even with a sense of total mastery," Kriss observed. "Their arm and body movements were free. I failed many times before succeeding even to approximate the feeling that they had achieved so effortlessly."

From the experience Kriss said he has learned a freedom in execution and to focus on free expression and the fun of painting. Impressed as would be any grandfather with his grandchildren, Kriss nonetheless realizes his children are not necessarily future Picassos. Instead, he said, there is a more important lesson.

"This talent is not unique to my grandchildren," Kriss said. "But as children get older, they are encouraged to copy and to put labels on everything. This particular aspect of creativity is inhibited."

Kriss's other works are also abstract, but much more geometric and self-admittedly much more restrained than those in the Faculty Club show. Kriss is scheduled to have another show at Los Robles Art Gallery in Palo Alto in late February.

VOLUNTEERS NEEDED FOR STOP SMOKING STUDY

STANFORD—

About 100 volunteers are being sought for a Stanford University Medical Center study of a new relapse prevention training program to help smokers stop smoking and stay quit.

"This program is designed for smokers who find themselves in a vicious quitting, relapsing cycle," said Robert Hill, who is directing the study under the auspices of the Stanford Center for Research in Disease Prevention. "In fact, smokers who have repeatedly tried to quit, but resumed smoking are expected to benefit the most," he added.

Researchers have found that of those smokers who initially quit, 70 to 90 percent will resume smoking before their first smoke free week, Hill said.

Participants will attend an intensive four week program designed to produce immediate cessation of smoking. They will then be divided into three groups to complete the study.

One group will use a system of self-administered positive rewards, such as personal praise and monetary incentives. Another will focus on negative imagery rehearsal which involves mentally recreating a negative relapse experience. The other will use a rapid smoking relapse prevention technique, said Hill.

Volunteers must be 18 or older, in general good health, and smoke at least a pack of cigarettes a day.

Meetings will be scheduled weeknights from 7:30 to 9, at Stanford, beginning Feb 21.

There will be a fee of $60 to cover costs of materials and fees of two psychologists who will be involved with the study. Pre-registration is required.

For information on how to participate, call Robert Hill, by Feb. 16, at (415) 497-2113.

TEACHING THROUGH PLAY LESSENS FEAR FOR HOSPITALIZED CHILDREN

Photos available on request if not included with story.

STANFORD—

Kristian Olson, almost 2, has a cabbage patch doll named Ollie to confide in whenever the doctor or nurse approaches with a needle. Ollie can understand because he, too, is a "patient" hooked up to an intravenous tube.

Kristian—who couldn't yet walk or talk eight months ago when he was first hospitalized—now tells Ollie what's happening to him in the course of his treatment for inflammatory bowel disease.

His mother and father have been constantly present. But besides their attention, Sam Olson believes much of his son's developmental progress is owed to Stanford University Hospital's recreation therapy program.

For parents the value of the playroom is basic, Olson said. "It gives the children a place to be. You can't just sit in your room. Kristian is active from morning till night.

"The atmosphere in hospital rooms is intense," he said. "The playroom is not so intense."

To achieve this, the recreation therapy staff, headed by supervisor Colette Case, concentrates above all on what hospitalized children can do, rather than what they cannot do. "We work with doctors, nurses and other professional staff as a team, to provide the most rounded-out and normal environment as possible for the child," Case explained. This helps parents too, as well as contributing to overall health care.

The hospital staff is often forced to look mostly at the pathology of a child's disease. While recreation therapists have some knowledge of anatomy, physiology, and medical terminology, "we look at the wellness of the child," Case said.

"We teach children about the hospital by having them play with miniature equipment, dolls and puppets—whatever they respond to, depending on their attention span and level of development," Case said. Using slides, photo albums and even a play hospital, "we direct the child's play to correct misconceptions."

Children play out what is to come, as well as what has already happened to them. In fact they play at being doctors as well as patients.

Alex Joshi, 4, placed a cast on a doll before undergoing his own leg surgery. When he recovers, he will remove the doll's cast, Case said. "It gives the child some control, and relieves anxiety and pain, to do to something what's being done to him." Also, she said, children rely on the sense of touch more than visually-oriented adults. Medical play allows them to touch and feel all the various gauzes, bandages, and other materials encountered in the hospital.

Olson said he is gratified that his son, who has had one operation and needs two more, is not afraid of people in the hospital and is doing well developmentally for his age. Kristian is hard to catch up with in the playroom, especially when clad in his Superman cape.

Olson, a carpenter, and his wife, a pediatrics nurse, choose to stay with Kristian all the time, taking 24-hour shifts. While many parents sleep in cots in the playroom, Olson said, "We sleep in a chair next to his bed—because he's so young and we're so protective."

Olson said he and his wife feel it is important to tell Kristian everything that is going to happen before it does. This has made a difference, he said, during the time that Kristian has been both at Stanford Hospital and Children's Hospital at Stanford.

Case adds, "If a bedridden child has IV tubing in both hands, parents often think there's nothing for them to do. Not true. The child can still listen to music or a story, or carry on a conversation.

"Basically, we try to provide psychological and social support to the child's care, while providing information to the staff about how the child is progressing developmentally," she said.

After five years in the Stanford Hospital program, Case is expecting her own first child in September.

"I plan to take a leave of absence and then come back," she said. "I couldn't be gone from this place for too long. You build up relationships with certain families who come back regularly over a period of time."

The program was started by Betty Lovelace, recreation therapist and a pioneer in the field, 16 years ago, Case said. Today Case, Lovelace, and two other certified recreation therapists handle the program, spreading themselves out over seven days and three evenings a week.

With many projects up their sleeves, the staff works continuously to improve their program. They are developing policies and rules to assure quality, which Case calls necessary to give the program a stable base.

In addition to chairing the patient teaching committee, which includes pediatric nurses, Case hopes someday to extend her special kind of insight to medical students—at least in the form of an orientation program.

"I'd love also to have a parents program, and a siblings program," she said. But those are long-term ideas.

Case visits area schools and teaches students about hospitals. "We go out about twice a month, often to special schools—for the orthopedically handicapped, for example—and if these children end up in the hospital, we know we've made a contact and it won't be as scary for them."

Case and her staff have visited various parents' groups as well, for families of children with special needs. This week being international Children and Hospitals Week, they join other staff in offering the community information vital to children's well-being.

PHOBIAS: HOW BEHAVIORAL MEDICINE TACKLES ONE OF MAN'S DARKEST TRAITS

STANFORD—

Fears and anxieties grip us all at one time or another. Snakes, heights, storms, doctors, sickness, injury and death—these are the seven most commonly reported fears.

Most of us learn to overcome our fears. They make sense because they protect us from danger. Fear leads to fast action and to flight. Fear instills caution in exploring new situations.

But for about 15 million Americans, fears can interfere with functioning. About one million—the same number as schizophrenics—are so disabled they cannot work outside the home or manage common tasks.

"Their fears become phobias," explains psychiatrist W. Stewart Agras of Stanford University Medical School. "A common event such as driving over a bridge, a picture of an accident or the sound of a police siren can trigger a severe panic attack."

Yet today a better understanding of phobias is within medicine's grasp, Agras says. With correct treatment in specialized clinics, more than 85 percent of patients with simple phobias can be cured after just a few visits. In some cases medications are used to help block panic attacks.

Phobias are nothing new. Throughout the centuries, fears have fascinated philosophers and writers because they provide an insight in one of man's darkest, most mysterious qualities. Doctors, however, gradually realized that the more intense of these disturbances were disabilities worth studying.

The term phobia, derived from the Greek god Phobos, who provoked fear and panic in enemies, was introduced in the 19th century. "And since that time," Agras adds, "it has been a field day for classifiers, who placed long and ponderous labels on each aversion."

Thus, we have the familiar claustrophobia or fear of enclosed spaces, and acrophobia or fear of heights, and the less familiar mysophobia or fear of dirt.

A 1969 study conducted by Agras in Burlington, Vt., showed that the most common fears begin in childhood, some in infancy. Women are more fearful than men in every category except the fear of injury, he said, perhaps because as children they are taught that it's acceptable for them to seek help and protection, whereas boys are taught "not to be sissies."

Agras, however, found that nearly one of 12 persons suffers from a mild to a moderate phobia, that more than two per 1,000 persons of the population is affected by a severe, incapacitating phobia, and that the phenomenon runs in families.

By far the most severe form is *agoraphobia*, which causes victims to have panic attacks and cling to a safe place. The condition has been called the "housebound housewife" syndrome, even though as many men as women suffer from it.

Jane (not her real name) was incapable of leaving home shortly after her marriage. Just a few yards away from her house she would become terrified, imagining that she might faint, choke, or even die if she did not return home at once.

"Jane's phobia," Agras explains, "could be traced to her childhood. Her sister had died after a brief illness, and her mother, fearful of losing her second daughter, constantly hovered over the child. As she grew up, Jane found her mother's attention comforting, even though it meant an overrestricted life.

"When Jane was 11, her mother was hospitalized for thyroid surgery after complaining of a choking sensation. The incident made a deep impression on Jane, who became fearful of choking and stopped eating solid foods. Jane's close identification with her mother—to the point of anticipating the choking symptom—and her fear of separation from her brought on her phobia, which she was unable to overcome in later years."

Agoraphobia is not very common in the general population, Agras says, "but it's the most common phobia we encounter in the Stanford University Clinic. Half the cases we see are agoraphobia victims suffering from intense panic attacks coming out of the blue."

Agras uses heart monitors, which his patients wear, to document their panic attacks as they experience them at home or elsewhere.

A panic attack, as he describes it, can be very frightening and resemble physical illness. "The victim gets a feeling of marked apprehension, the heart rate jumps from 90 to 150 beats per minute, breathing is difficult, and there's some chest pain or ache in the stomach. The attack lasts about 20 minutes and leaves the person shaken."

A common scenario afterward, Agras explains, is that the victim visits a doctor, who finds nothing physically wrong. It may take many attacks before they are recognized as a panic syndrome and treatment is arranged.

Failure to diagnose the phobia is not without consequences, he notes. "The longer the phobia persists the more difficult it is to break. Over time some phobics resort to compulsive rituals to ward off panic. The measures not only prevent the patient from coming to grips with the feared object, but they can be as debilitating as the panic itself."

Another problem hampering early diagnosis is the phobics' tendency to hide their fears because "in our society they are considered a sign of cowardice," the psychiatrist says. Fortunately, he adds, articles in the popular press have helped create a better understanding of the problem.

For many years, psychiatrists attempted to treat phobias based on Sigmund Freud's theories. The idea was that through classical psychotherapies a patient could uncover the underlying conflict and the phobia would vanish. Unfortunately, this approach has not worked well and for years phobias have been frustrating disorders to untangle.

The new treatments for phobias do not bother with analysis or psychotherapy. Instead, they concentrate on changing behavior through gradual exposure to the feared situation or object. "The reward," Agras explains, "is the therapist's continuous feedback and praise and the patient's own feeling of accomplishment at conquering his phobia."

These so-called behavior modification techniques are based on psychologists' observations over the past 15 years that behavior is often controlled by events in the environment.

"Suppose we are dealing with someone who has fear of heights," Agras explains. "We find a building several stories high with an outside fire escape. We arrange a field trip for the patient and therapist. The therapist asks the patient to walk up as far as he can without undue fear. Next the therapist asks him to look over the edge, expose himself to the downward view, then walk up another few steps. As he makes progress the patient is praised. If not the therapist is silent.

"The patient's exposure to a gradually scarier situation allows his anxiety to dissipate. Eventually, he walks alone with self-confidence and a sense of independence."

Sometimes a therapist works with small groups of patients. In more serious phobias, Agras involves the patient's spouse in the therapy process. "We provide a manual which teaches the spouse to be a therapist," he explains.

Treatment may involve both exposure therapy and medications such as the antidepressant, Imipramine, which wards off panic attacks. In some instances, hypnosis and muscle relaxation are used.

Agras and Drs. Michael Telch, C. Barr Taylor, Walton Roth and Christopher Gallen of the Laboratory for the Study of Behavioral Medicine recently tested combined exposure and drug therapy in 37 severely disabled agoraphobics. The patients were divided into three groups. One group received Imipramine but no exposure therapy, another received the drug and therapy, and the third group was given a placebo plus exposure. At 26 weeks the combined treatment had obtained superior responses in patients than either of the other methods.

In the future, Agras predicts, more and better antipanic agents will be developed. "Meanwhile, the differences between various treatment approaches simply boil down to the way in which the patient is induced to go out and actively confront the phobic situation."

LECTURES ON WOMEN'S HEALTH CARE ISSUES

STANFORD—

The Spring 1985 Women and Health Friday Noon Lecture Series at the Stanford University School of Medicine begins April 5.

The series, sponsored by the Division of Family, Community and Preventive Medicine, is open to the public, free of charge, and will be held in room M114, from 12:00 to 1:00 p.m.

The lectures will provide an interdisciplinary forum on women's health care addressing some of the topics which are not usually covered in medical education and research, said Marita Grudzen, the division's program manager.

"Lectures were chosen in response to requests from people who previously attended the Women and Health Series and were interested in topics such as minority women, health issues related to lifestyle, and other controversial issues," Grudzen said.

The lectures are:

- April 5, "Women and AIDS," Pat Norman, coordinator, Lesbian-Gay Health Services, City and County of San Francisco.
- April 12, "Southeast Asian Refugee Women," Dr. Evelyn Lee, assistant clinical professor of psychiatry, University of California at San Francisco (UCSF).
- April 19, "Different Strokes for Different Folks: Conception versus Contraception for Minority Adolescent Women," Elizabeth Ynzaga, practicing nurse midwife, Freestanding Birth Center.
- April 26, "Seventeen Years of Health Activism," Pat Cody, economist; one of the founders of DES Action.
- May 3, "Everyday Labor: Mothers, Work and Money," Julie Olsen Edwards, director, department of early childhood and family life education, Cabrillo Community College.
- May 10, "The Pre-menstrual Syndromes: What Are They and What Can Be Done About Them?" Dr. Carol Jessop, assistant professor of medicine, UCSF.
- May 17, "Lesbian Health Care Needs: The Forgotten Women," Dr. Carol Jessop, medical director, Lyon-Martin Clinic.
- May 24, "Double Stigma: Lesbians with Chronic Disease," Dr. Susan Browne, nurse consultant in private practice.
- May 31, "The Health of Hispanic Women — A Non-Hispanic Woman Physician's Perspective," Dr. Paula Braveman, assistant clinical professor of family and community medicine, UCSF.

A discussion group with case presentations will be held for enrolled students following each lecture, from 1:15 to 2:00 p.m., with the speaker, and Grudzen, Dr. Jeanne DeJoseph, assistant director of nursing at Stanford University Hospital, and Dr. Judith Martin of the Division of Family, Community and Preventive Medicine.

For further information call Grudzen at 497-7066.

COLD SORE, HERPES SUFFERERS SOUGHT AS RESEARCH VOLUNTEERS

STANFORD—

Persons suffering from recurrent cold sores, fever blisters or herpes sores of the lips, mouth, face, arms, legs or body (not genitals) are being sought for a Stanford Medical Center study.

Dr. John W. Torseth of the Division of Infectious Diseases, said about 50 volunteers were being recruited for the project, which is aimed at determining why these maladies recur so that ultimately a vaccine might be developed to prevent them.

About 40 percent of the population has evidence of exposure to herpes, while about 8 percent of the population has recurring sores or symptoms, Torseth said.

The volunteers will be asked to visit the Medical Center either once or twice for the drawing of a small amount of blood and a brief physical examination, Torseth said.

For further information contact Torseth at (415) 497-5909 or 497-5715 between 8:30 a.m. and noon on weekdays.

The study is being sponsored by a grant from the National Institutes for Health.

BOOKLET PROVIDES FACTS ON STANFORD MEDICAL CENTER

STANFORD—

Did you know that more than 70 people a day come to Stanford University Hospital for emergency care?

Or did you know that the combined budget of the Stanford University Medical Center (School of Medicine, Clinic and Hospital) in fiscal 1984 was more than $357 million?

Were you aware that in 1960 the average length of hospitalization at Stanford was 13.3 days, but by 1984 it had dropped to 6.9 days?

If you are interested in life-saving cardiopulmonary resuscitation techniques, did you know that the hospital's Life Support Training Center could train you free of charge?

These items and other pertinent information appear in the 1985 edition of *Facts*, a 32-page booklet published by the Office of Communications of the Stanford University Medical Center.

The booklet describes the programs of the medical center and provides a glimpse of its history, accomplishments, highlights of patient services, educational programs and ongoing research.

The booklet also provides useful telephone numbers ranging from clinic registration information to patient relations services.

If you wish to obtain a copy, contact the Office of Communications at 415: 497-6911.

FOR IMMEDIATE RELEASE

DEAN APPOINTS SEARCH COMMITTEE TO FILL MEDICINE CHAIRMANSHIP

STANFORD—

Dr. Hugh O. McDevitt, professor of microbiology and medicine, will head the search committee for a new chairman of the Department of Medicine.

The 14-member committee, which will include one student yet to be named, was announced Tuesday, March 19, by Dr. David Korn, dean of the Stanford University School of Medicine.

The committee, Korn explained, is expected to conduct a comprehensive and far-reaching search to identify three or four outstanding candidates and recommend them to him for consideration.

The Department of Medicine with 13 academic divisions and extensive clinic and hospital-based practice, is one of the largest medical school departments. It is responsible for the teaching of a large proportion of medical courses, ranging from physiology to subspecialty clinical clerkships. It also provides postgraduate training for resident physicians and fellows in specialties and subspecialties of medicine both at Stanford University Hospital and its affiliated institutions.

The department is internationally recognized for its research in the areas of cancer, clinical pharmacology, immunogenetics, lipids and lipoproteins, metabolism, blood disorders, respiratory medicine, kidney physiology and cardiology.

The department has been without a permanent leader since Dr. Kenneth Melmon, its chairman since 1978, resigned last July. In the interim, the department has been headed by acting chairman Rex Jamison, professor of medicine and head of the Division of Nephrology.

In a letter, Korn urged committee members to seek opinions on potential candidates from colleagues both inside and outside Stanford.

"The important attributes to seek are a suberb record of scholarship, demonstrated commitment to the education and training of medical students, housestaff, fellows and faculty in all areas traditionally subsumed under medicine, excellence in clinical care and broad knowledge of changes in the direction and governance of clinical care."

Candidates for the post must demonstrate skills in providing administrative leadership for a large heterogeneous department, Korn stressed.

In addition to McDevitt, committee members include Ann Arvin, pediatrics; Thomas Fiene, medicine; Robert J. Glaser, medicine; Dora Goldstein, pharmacology; Dale Kaiser, biochemistry; Richard Kempson, pathology; Sheldon King, Stanford University Hospital; William Northway, diagnostic radiology; Harry Oberhelman, surgery; Lawrence Steinman, neurology; Donald Stanski, anesthesia; and Lubert Stryer, cell biology.

SERIOUS INFECTION MAY BE TREATABLE WITH NEW HUMAN MONOCLONAL ANTIBODY

STANFORD—

Scientists at Stanford University School of Medicine and the University of California, San Diego (UCSD) have developed a potential treatment for a bacterial illness that is a leading cause of death from infection in the hospital, estimated to kill 75,000 Americans annually.

The illness is a bacterial bloodstream infection called gram-negative sepsis. The potential new treatment consists of a protein that neutralizes endotoxin, a poisonous substance released by the bacteria that cause the infection.

The protein, a human monoclonal antibody, is highly effective in protecting animals from bacterial endotoxin-induced sickness and death.

It is thought to be the first human monoclonal antibody demonstrated to have therapeutic promise and biological effectiveness, the scientists said. It will be tested in humans sometime within the coming year, they added.

Production of the antibody was reported in the March issue of the scientific journal *Proceedings of the National Academy of Sciences*.

The scientists involved were Dr. Nelson Teng and Dr. Henry Kaplan of Stanford University School of Medicine, and Dr. Abraham Braude of the UCSD School of Medicine. Drs. Kaplan and Braude died before the research was published.

Other researchers include Joan Hebert, and Cynthia Moore of Stanford, and Herndon Douglas and Annette Wunderlich of UCSD.

Funding for the research was provided in part by the Robert L. Seidner Research Fund, the National Institutes of Health, and the National Cancer Institute.

A monoclonal antibody is a protein capable of targeting for destruction specific substances in the body. The human monoclonal antibody molecule developed by Teng and his colleagues is made in the laboratory by special cells called heteromyelomas. The monoclonal antibody specifically binds to and inactivates bacterial endotoxin molecules.

Endotoxin is a substance found on the surface of certain bacteria such as Escherichia coli, an organism that lives in the human digestive tract. In healthy people, these bacteria are harmless because they are kept under control by the body's immune system.

But disease, surgery or other conditions that weaken the immune system sometimes permit the bacteria to break through a patient's defenses. This can lead to bloodstream-borne infections called bacteremia and endotoxemia that sicken an estimated 200,000 people and kill 75,000 each year in the U.S. alone, said Teng, an assistant professor of gynecologic oncology.

2-2-2 Endotoxin produced by the invading bacteria causes fever, relaxation of the blood vessels, lowered blood pressure, and leakage of serum fluid into the lungs. Eventually this can cause severe or fatal shock and respiratory distress or circulatory collapse, Teng explained.

In the laboratory, the newly engineered monoclonal antibody was effective in preventing death in animals injected with a wide variety of unrelated gram-negative bacteria that produce endotoxin, the researchers reported. (Gram-negative refers to a class of microorganisms that do not absorb a special stain.)

Although different gram-negative bacteria may produce slightly differing forms of endotoxin, the new antibody is thought to be capable of neutralizing them all because it recognizes a portion of the molecule that is common to all.

Because of this versatility, the researchers hope that it will be of broad clinical use.

Although gram-negative bacteria can be killed by antibiotics, the drugs cannot fight the endotoxin poison released by the bacteria. This means that antibiotics are not effective against severe bacteremia and endotoxemia, Teng said. Antibiotics may even make matters worse because dying bacteria can release vast quantities of endotoxin into the patient's bloodstream, Teng said.

Several years ago, Braude, Dr. Elizabeth Ziegler and their UCSD colleagues reported that human blood serum containing antibodies against endotoxin could cut the death rate in half among hospitalized patients with gram-negative bacterial sepsis, Teng said.

But using blood products opens up the potential for transmitting diseases such as hepatitis, cytomegalovirus and AIDS, because the serum is obtained from vaccinated volunteers, he added.

The new antibody, on the other hand, could be produced in pure form and in the large amounts needed for clinical use without the inconveniences, expense, and risks of human vaccination and antiserum collection, Teng said.

Clinical tests of the antibody will probably begin in hospitalized patients who acquire gram-negative bacterial infections, Teng said.

Underlying diseases or conditions that may make patients more vulnerable to endotoxin include diabetes, cirrhosis, cancers such as leukemia and lymphoma, transplantation surgery, and infections of the urinary or gastrointestinal tract, Teng said. Premature infants with immature immune systems are also at risk, he added.

Teng said the researchers expect very few side effects from administration of the antibody.

In laboratory studies the new antibody was tested for its ability to neutralize endotoxin. In rabbits injected with endotoxin, the scientists observed that a specific type of skin damage caused by the substance was prevented in nearly all the animals that were also given injections of the monoclonal antibody.

In another lab study, the antibody was tested for its ability to protect mice infected with gram-negative bacteria. Two groups of mice were infected with gram-negative microorganisms. One group was given the monoclonal antibodies against endotoxin while the control group received mock antibody, Teng said.

Up to 150 times more bacteria were required to kill half the mice given the monoclonal antibody than were needed to kill half of the animals given the mock antibody, the researchers observed.

"This human monoclonal antibody has broad reactivity to all gram-negative bacteria tested without exception and has been demonstrated to provide potent protection of lethal bacteremia," they wrote.

"Such a monoclonal antibody should hold great promise in both analysis and treatment of gram-negative bacteremia and endotoxemia," the researchers concluded.

FAIRLEY APPOINTED ANESTHESIA HEAD

STANFORD—

H. Barrie Fairley, a British-born physician who has researched techniques to support hospitalized critically ill patients, has been appointed chairman of the Anesthesia Department at Stanford University Medical School effective April 1.

Fairley comes from the University of California at San Francisco, where he has served as vice chairman of anesthesia since 1972. His Stanford appointment as tenured professor was approved by the Board of Trustees on Tuesday (March 12). His simultaneous appointment as chairman was announced by Dean David Korn.

The Department of Anesthesia is comprised of 39 faculty physicians who provide anesthesia services at Stanford University Hospital, Palo Alto Veterans Administration Hospital and Santa Clara Valley Medical Center. Fairley said he will seek to continue the department's substantial commitment to clinical anesthesia service while expanding the existing research effort, which is underway at all three facilities.

Fairley replaces C. Philip Larson, who resigned as chairman effective Dec. 1, 1982 but remained on the faculty to continue his clinical, teaching and research roles. John C. Bunker, professor of anesthesiology, served as acting chairman until he left for a sabbatical leave Oct. 1. The most recent acting chairman was Ellis N. Cohen, professor of anesthesia emeritus.

A 1949 graduate of the Westminster medical School of the University of London, Fairley came to UCSF in 1969 after 14 years at the University of Toronto.

In a summary of his work prepared by university staff for the trustees, Fairley was praised for "important scientific contributions to the fields of Anesthesia, Respiratory Physiology and Care of the Critically Ill patient. Most influential has been the impact of his scientific investigations in the development of the interdisciplinary intensive care unit with the ability to manage patients in acute cardiorespiratory failure."

Fairley has already begun part-time duties at the medical school pending the start of his full-time appointment as chairman.

PUBLIC WARNED OF BOGUS RESEARCH CALLER

STANFORD—

A telephone caller misrepresenting himself as a Stanford University researcher has recently been asking Bay Area women intimate questions under the guise of a scientific survey, security personnel have reported.

Larry Jordan, assistant director of security at Stanford Medical Center, said three Peninsula residents have complained to various medical center offices that a telephone caller posed sexually oriented questions to them. The caller, Jordan said, said he was conducting research under the auspices of the medical center and Planned Parenthood.

Both Stanford and Planned Parenthood have disavowed any involvement with the study.

Norah Holmgren, a spokeswoman for the Planned Parenthood Federation of America, Inc., Western Region in San Francisco, said she has told local affiliates of her national oganization to advise women to be aware that misrepresentation of research has been reported.

Jordan said the Palo Alto Police have been notified, and "people who receive these phone calls should respond just like they would for any other obscene phone call—hang up and report the incident to police."

Stanford issued a similar warning in June 1981, after several women phoned the university to verify the authenticity of a caller who misrepresented a Stanford and Planned Parenthood connection.

Kathy Callahan, administrative coordinator for the medical center's Human Subjects Committee, said no study initiated by a telephone survey of sexual habits is currently under way. All Medical Center research involving the public must be reviewed and approved by the Human Subjects Committee, she added.

Callahan said any approved research involving telephone surveys requires that the interviewer describe the content of the study in detail, and then inform the respondent who specifically is conducting it. Participants must be reassured that they are under no obligation to participate.

Persons who receive calls from individuals persons who state they are Stanford researchers may call the Human Subjects Committee (415) 497-5244, to verify the authenticity, Callahan said.

Currently, about 2,000 projects of various complexity have been approved by the human subjects committee. Only a handful involve telephone surveys, she said. No study involves only explicit questions about respondents' sexual behavior. Such questions are only posed as followups to persons already enrolled in an ongoing study, she added.

WEIGHT CONTROL COURSE SCHEDULED

STANFORD—

An eight-week course on weight control is being offered in six sessions this year and early 1986 by the Stanford University Hospital Department of Dietetics.

"An Enlightening Experience," led by registered dietitians, includes a personalized weight loss plan, low calorie cooking demonstrations and recipes, menu planning and tips on dining out wisely, said dietitian Kristine Birge. Guest speakers in the program will discuss stress reduction, behavior modification techniques and exercise, she said.

Participants may register for either afternoon or evening sessions to be held in the hospital's north cafeteria dining room. The first evening class will meet 7:30 to 10 p.m., Tuesdays, April 23 through June 11. The first afternoon class will meet 1 to 3:30 p.m., Thursdays, April 25 through June 13.

Other afternoon starting dates include Sept. 26 and Jan. 16, 1986. Additional Tuesday evening sessions start Sept. 24 and Jan. 14, 1986.

Enrollment for each class is limited to 20 participants. The fee is $325 with a $50 refund if the individual's weight goal is achieved. Registration deadline for the first session is April 19.

For further information, call (415) 497-5432.

FOR IMMEDIATE RELEASE

STANFORD WILL CONTINUE ITS OWN AIDS SCREENING ALONG WITH NEW TEST

STANFORD—

Stanford University Blood Center plans to continue using its own screening test for AIDS even after a newly developed and highly publicized test becomes available here in about a month, an official said Tuesday (March 5).

"We're very interested in this new test, and we are anxious to begin testing it to determine if it is effective. But we are not going to throw out the successful and highly accurate test we have been using for 19 months until we get some hard evidence that the new screening is at least as accurate as what we have now," said Edgar Engleman, associate professor of pathology and medicine and medical director of the blood center.

On July 1, 1983, Stanford reportedly became the first blood bank in the nation to begin screening blood for the deadly AIDS, short for acquired immune deficiency syndrome. Since then, no cases of AIDS have been reported in Stanford Blood Center recipients who received the screened blood, although two recipients who had received blood from several centers, including Stanford before the procedure was begun here, subsequently contracted AIDS and one has died, Engleman said.

"Stanford was able to pioneer screening because as a research center the specialized equipment and expertise is available to conduct the test," Engleman said.

Using monoclonal antibodies—specially manufactured proteins—and a sophisticated $200,000 research tool called a fluorescence activated cell sorter (FACS), the blood center is able to detect an abonormal ratio in the white blood cell composition which is common to AIDS patients. Cost of running the test, he said is about $6 per donor.

A drawback to the Stanford test, said Engleman, is that the abnormal ratio of "suppressor T-cells" to "helper T-cells" detected in the test is also present in some persons who do not have AIDS. Therefore, healthy donations from about 1.5 percent of the Stanford Blood Center's 18,000 annual donors must be eliminated because their test results are positive.

3-5-85 -more-

Other Bay Area blood centers announced this week that they would begin using another test, called HTLV-III, which measures the presence of antibodies to what is believed to be the AIDS virus.

Engleman said that this test is more specific, because it tests for evidence that the patient actually has been exposed to AIDS, rather than for the highly accurate but indirect evidence of measuring T-cell ratios.

Eliminating some healthy blood is an unfortunate but necessary result of the screening process, Engleman said.

"Obviously when you deal with a disease as deadly as AIDS, it is essential to err on the side of caution," Engleman said.

Some healthy blood might also be eliminated using the HTLV-III test, which would screen out persons whose antibodies have successfully fought off exposure to AIDS, Engleman said.

"Also, we want to make absolutely certain that persons who actually are AIDS carriers will not slip through the screening process, and we won't know that with a reasonable degree of certainty until we test this new screening process for awhile," he said.

Testing of the HTLV-III screening will begin at Stanford after Abbott Laboratories Inc., of North Chicago, Ill., makes the serum available within a month, Engleman explained.

In a related matter, Rhoda Burns, Stanford's blood donor coordinator, said donations have dropped about 4 percent in the last several months to an average of 1,550 units.

"People don't seem to realize that all collection of blood is done with disposable equipment and that there is absolutely no risk of contracting AIDS or any other infection from donating blood," said Burns.

"Healthy blood donors will result in healthy blood recipients," she added.

Burns said that members of high risk populations, including gays, have been "very responsible locally in deferring themselves from being blood donors at this time." The decrease in donors, she said, is significantly greater than what would be accounted for by the voluntary withdrawal of potentially high risk donors.

ADVANCE FOR RELEASE 2:30 P.M. (PST) THURSDAY, MARCH 7

EDITORS: Paul Williams and perhaps other researchers involved in the study will be available at 10:30 a.m. Thursday, March 7 for a news conference to discuss the findings. Call the News Bureau at (415) 497-6911 for the location of the news conference.

COFFEE CONSUMPTION AND CHOLESTEROL LINKED IN NEW STANFORD STUDY

STANFORD—

Men who drink three cups of coffee or more per day have higher cholesterol levels than those who drink two cups or fewer daily, according to a new study by Stanford University Medical School researchers.

Heavy coffee drinkers also have higher levels of apolipoprotein B, a cholesterol-associated protein that is linked to heart disease, the study found.

It is the first study to show an association between coffee consumption and apolipoprotein levels, said Paul Williams, director of data management for the Stanford Center for Research in Disease Prevention.

And it is the first U.S. study to show a significant link between cholesterol levels and coffee drinking, although previous European studies have suggested such a relationship, Williams said.

The study was scheduled to be published in the March 8 issue of the *Journal of the American Medical Association* by Williams and his colleagues Dr. Peter Wood, research professor of medicine; Karen Vranizan, research assistant; Susan Garay, project coordinator; Dr. Barr Taylor, associate professor of psychiatry; and Dr. John Albers of the University of Washington

Williams stressed that the study does not prove that drinking coffee causes cholesterol levels to rise. But when other factors that could contribute to high cholesterol levels were taken into account—such as diet, age, obesity, stress, and cigarette smoking—the correlation was even stronger, he said, suggesting that coffee drinking may increase cholesterol levels.

Coffee intake was most strongly linked to elevated levels of apolipoprotein B, Williams said, but it was also associated with higher levels of low-density lipoprotein (LDL), a type of cholesterol, and total plasma cholesterol, all of which are considered important risk factors for cardiovascular disease.

Coffee consumption above approximately three cups per day seems to mark a risk threshold, Williams said. The group that consumed more than three cups had clinically high levels of all three of these risk substances, Williams said.

The results contradict previous U.S. studies that have found no significant link between coffee consumption and cholesterol, Williams said.

But there are several features of the Stanford study that could account for this difference, Williams said.

In previous studies, researchers looked at total plasma cholesterol levels, he said, while in the Stanford study the researchers looked at blood levels of specific cholesterol components, such as LDL, as well as examining total plasma cholesterol levels.

Also, the men in the Stanford study kept careful diet records over a period of three days, unlike previous study groups. In addition, the Stanford study took into account other factors that could have raised cholesterol, such as age, cigarette smoking, obesity, stress, and diet.

The 77 male subjects in the study kept track of coffee consumption and other dietary intake over a period of three days. They ranged in age from 30 to 55 years; all were sedentary and most were Stanford University employees.

Eighty-nine percent of the group drank coffee, and 91 percent of the coffee consumed was caffeinated and brewed from regular grounds. The average number of cups consumed daily was 2.6, and the maximum daily intake was 7.5 cups.

Apolipoprotein B, which was most strongly correlated with coffee intake, is considered one of the more important predictors of heart disease, Williams said. It is a protein that is part of the LDL particle. It is thought to help LDL dissolve in blood and it may play a role in the uptake of LDL into cells.

Levels of LDL, the type of cholesterol most strongly linked to heart disease, were also associated with coffee intake and finally, although less striking, there was also a link between overall plasma cholesterol—which includes LDL and other components—with amount of coffee consumed.

Williams said the European studies may have found a coffee-cholesterol connection earlier because the populations they studied may have drunk more and stronger coffee than do most Americans.

Williams noted that since the current study was limited to sedentary middle-aged men, further studies are needed to determine whether similar associations will be found in other segments of the population.

In addition, he stressed that more research is needed to prove conclusively whether or not coffee itself is a cause of the high cholesterol levels. Such a study is in the planning stages, he noted.

Williams said that if coffee turns out to be the culprit, a next step will be to pinpoint what substance in coffee is responsible. There are lots of things in coffee, he pointed out, not just the most frequently cited caffeine.

The research was supported by funds from the National Heart, Lung and Blood Institute.

STANFORD RESEARCHERS TEACH KIDS TO ARGUE FOR GOOD HEALTH

STANFORD—

The threat of bad breath may be a better argument than the threat of cancer in turning off teenagers to smoking, say Stanford researchers conducting a study in how to help kids develop good health habits.

"The idea is to catch youth before they develop bad living habits," said Nathan Maccoby of the Stanford Center for Research in Disease Prevention. "If they don't develop these bad habits in the first place they've got nothing to break when they grow older."

"If you tell a kid not to smoke because he may get cancer you won't have much of an effect," said Dr. Michael Telch, a Stanford behavioral scientist who together with Dr. Joel Killen is directing the study. "But if you tell him it's an expensive habit and smoking will cause bad breath and turn off girls, that'll mean something." Especially, Telch added, when the information is combined with skills for resisting pressures from peers and advertising.

"What we want to achieve is a 'psychological innoculation'," Maccoby said. "We want to arm youngsters in such a way that they can resist the pressures of smoking, for example."

The study, based on decades of research by Maccoby and colleagues, is aimed at teaching high schoolers, beginning in their sophomore year, how to resist the use and abuse of substances such as tobacco, drugs and alcohol. It's also intended to teach kids to adopt good eating habits, exercise programs and stress management techniques.

The teaching takes many forms such as information and role play. It also shows kids how to resist pressures from peers and advertising by being able to come up with counter arguments, a technique developed and proven effective by Maccoby and other scientists throughout the country.

"Knowledge alone is not enough to change behavior," Telch explained. "Kids need the behavioral skills in order to change. They need to know they can exert control of their behavior.

"Tenth graders are a good group to teach behavioral skills because they're at an age when they're starting to pull away from their parents a bit and take some control of their lifestyles," he said.

The study, funded by a grant from the National Heart, Lung and Blood Institute, involves four high schools in the South Bay area. It includes a 23-session program incorporated in the students' daily curriculums. The sessions are led by specially trained Stanford graduates who, according to Telch, are "bright, young, attractive—good role models for the kids."

The study is the latest in a series expanding upon Maccoby's concept of counter arguments, which he started researching during World War II. After many experiments, he found that if people knew both sides of an issue in deciding which side they believed, and had the opportunity to argue against opponents of their beliefs, they were much less likely to be persuaded to the other side.

Maccoby, Telch and colleagues established this fact in a study in which seventh graders were trained to resist smoking through counter arguments. Seventh grade kids were chosen, Maccoby said, because it's during that school year that the most experimentation with smoking takes place. Specially trained high school students led seven sessions in one seventh grade class throughout the year, while another class received no instruction as a source of comparison.

The results, published in the *Journal of Behavioral Medicine* in 1982, showed that at the completion of the nine-month-long school year 5 percent more kids who did not receive training smoked than those who did have the training. And a year later, the percentage of kids who did not undergo the training increased from about 10 percent to 18 percent, while the percentage of those who underwent the training barely increased from about 5 percent to 7 percent.

"Being trained in counter arguments can be useful in situations throughout one's life," Maccoby said. "People say you need will power. Well, we're teaching it."

APPLE'S MACINTOSH COMPUTER HELPS APHASIC VICTIMS COMMUNICATE

STANFORD—

Aphasia victims may some day be able to communicate with others using a special pictorial language, Apple's Macintosh computer and its mouse, according to Stanford University scientists.

"The Apple Macintosh is best suited for our needs because it has high resolution graphics and is easily programmable," said neurologist Dr. Michael Weinrich. "It's also relatively affordable and portable. Together with the mouse, it's the perfect system."

In what may be the computer's first medical application, the Macintosh is already helping 45-year-old "JN", who hasn't been able to "talk" to anybody since a motorcycle accident nine years ago damaged the left side of his brain, wiping out his ability to read or speak.

But that may soon change. For several months now, JN has been learning to use the Visual Communications System for Aphasics. The system consists of "stacks" of symbols on a computer screen that JN can "flip" through by using the mouse, a hand-manipulated device that eliminates the need for a keyboard.

JN travels from his South San Jose home to the Rehabilitation Research and Development Center at the Palo Alto Veterans Administration Medical Center twice a week for training sessions on the system. JN is one of two patients currently working with Weinrich, linguist Richard Steele, graduate hearing and speech pathology student Judy Illes and others to regain the ability to express the simplist needs, "I want a drink," to more complex questions, "Do you have a can opener to give to me?" .

"He can't wait to come up here each day," said JN's father, who lives with and helps care for the stockily built man, balding and greying at the temples. "He knows he'll soon be able to talk with people that come to the house. That's what keeps him going."

JN is aphasic, one of thousands each year who suffer brain damage most commonly due to stroke or trauma, Weinrich explained. Some victims lose the ability to express their own thoughts. Other lose the ability to understand what is being said to them as well.

Corresponding with the loss of communication, Weinrich continued, is some paralysis of the right side of the body, which often leaves victims with only one fully functioning hand.

Past attempts to teach aphasics to communicate have often failed, Weinrich said, because they have been structured on ordinary verbal language, the comprehension of which takes place in the left side of the brain, which has been damaged. However they can recognize pictures and symbols, the comprehension of which takes place in the right side of the brain. Yet attempts to teach aphasics the language of symbols, typically drawn on flashcards, have met limited success because the paralysis makes the flashcards awkward to handle.

-more-

"It was too difficult for patients to flip through a pile of flashcards with only one hand," Weinrich noted. "And the langugage was limited in order to keep the number of flashcards more manageable."

Enter high technology. By programming all the symbols into a computer, the scientists eliminated the need for the flashcards. And the mouse enables patients to operate the system in spite of their limited coordination.

Sure enough, JN's right hand lies motionless in his lap while with his left hand, he operates the mouse to move the cursor on the screen to each stack of symbols, organized into categories such as nouns, verbs and punctuation. Each push of the button on the mouse brings up the next symbol in the stack faster, it seems, than a blink of an eye. Once the desired symbols appear, JN moves the mouse to freeze their presence, thus forming sentences.

In order to allow JN to communicate with people who don't know the symbol language, linguist Steele incorporated programming into the system that prints the English translations below the pictorial sentences.

Patients like the system, Weinrich said, because of its speed and simplicity. Its flexibility, he added, encourages them to express more complex thoughts rather than just sticking to the bare minimum.

The scientists, who have been working on the system since last July and have been training patients on it since February, are continually expanding its vocabulary and capabilities. What they'd like to do, they said, is to program into the system pictures of actual places—the rooms in a house, for example. By using the mouse, "the patient could pick a room such as the kitchen to appear on the computer screen," Weinrich explained. "In the kitchen would be all the usual appliances. The patient could hone in on the refrigerator, let's say, open the door, and pick out the product—perhaps a jar of mayonnaise—that he wanted."

The scientists also see the possibility of programming a scratch pad into the system that could appear on the screen so users could develop their own symbols if needed. They even envision a hook-up to a voice synthesizer, which could allow aphasics to "talk" on the phone.

"What we hope to create," Weinrich said, "is a computer program and instruction manual for others to use to teach aphasics how to communicate."

What JN hopes for, his father said, is to go beyond the grunts and gestures he's developed to get his needs across to his dad, just about the only person who can understand him. He's anxiously awaiting the day he'll be able to "talk" to someone "who has come by the house to visit."

LANE MEDICAL LIBRARY 'ALARMINGLY INADEQUATE,' REPORT SAYS

STANFORD—

Stanford School of Medicine's Lane Library, a central place in the training of physicians and one of the nation's major repositories of medical information, is "alarmingly inadequate," says a report of the library committee.

The library will have to be replaced in the near future to maintain excellence and fulfill its mission, the committee said.

"The lack of space interferes seriously with our ability to provide up-to-date services to students, faculty, medical staff, the university and our affiliated institutions," agreed Dr. David Korn, dean of the School of Medicine. "Providing sufficient growth space for the library is critical to our long range agenda."

Lane Library's collections rank tenth in size among the nation's medical school libraries, said Dr. William Northway, professor of radiology and committee chairman, yet Lane, with the exception of one East coast medical school, has the smallest facility in net square feet, the smallest staff of librarians and the least space per user of books among the top 10.

The paucity of space, insufficient number of librarians, and lack of room for future collection expansion were also noted by the Liaison Committee on Medical Education (LCME), an accreditation team which reviewed the medical school last year. The school received full accreditation, but it has been required to present to the LCME a plan for solving the problems of overcrowding in the library and to develop an approach for the application of automation technology.

"The staff problem is not simply budgetary," Northway said. "There is no space to put the staff and new service programs."

Northway reviewed the library's status last week before the school's academic leaders who make up the executive committee. "Although the dean will allocate 3,000 to 5,000 square feet of space to temporarily ease the situation, the library will run out of room to house its collection within five years," he said.

Part of the library's problem is that it is "land-locked" and cannot expand, Northway explained. The committee examined the feasibility of filling a courtyard within the library on two levels to add 12,000 square feet. That solution, however, is insufficient to meet future needs and costs would be greater than new construction.

4-30-85

-more-

In spite of the difficulties, Lane's staff was praised highly by the accreditation team for the quality of services it provides. The report added the library's collections are still excellent. But library funding is only adequate for maintaining the current level of staffing and collection development.

A review document prepared by Librarian Peter Stangl and his staff states that for several years library funding has not provided for growth in services. With the addition of new academic programs, the library will not be able to provide services at current levels.

"The development of a new Center for Molecular and Genetic Medicine and other programs now planned by the school should be expected to saturate the library's resources," Stangl told the school's executives. "There's a flash point we will be soon approaching."

As the volume of published information continues to grow, Stangl said, the pressure on research libraries to provide progressively more sophisticated information services has increased. Both the publishing industry and the research library community have been looking to computer technology to help relieve pressures of workload and costs.

As a result, Lane Library is moving ahead with a procurement decision for an automated library system. "Basically, this involves a computer-based integrated system that combines on-line circulation, cataloguing, acquisitions and MEDLINE," said David Mendelow, associate dean for administration. The library has been using MEDLINE, a computerized data base of journal articles produced by the National Library of Medicine that permits faculty and staff to do literature searches. The new integrated system will provide local access to such data base."

This first step, Mendelow said, means simply that terminals will replace card catalogs, and faculty, medical staff, researchers and students will gain access to the library from their personal computers on their desks.

Lane Medical Library, established in 1912 by the directors of Cooper Medical College, forerunner of the Stanford medical school, was originally in San Francisco. The library was relocated to the Stanford campus in 1959 when the medical school was moved to the new Stanford University Medical Center constructed by architect Edward Durrell Stone.

HEALTHY VOLUNTEERS SOUGHT FOR KIDNEY STUDY

STANFORD—

Healthy, non-smoking men aged 18 to 40 who are taking no medications are being sought for a study by the Division of Clinical Pharmacology at Stanford University Medical Center.

The study is an attempt to determine how a common antifungal drug, ketocomazole, is removed from the body by the liver. Principal investigator is Dr. Terrence Blaschke, associate professor of medicine and pharmacology.

Six volunteers will make five visits of 48 hours each to a research unit at the medical center, where they will receive oral doses of ketocomazole. Blood tests, saliva and urine samples will be taken at each visit.

Prior to the first overnight visit, a complete physical examination, including laboratory tests, will be conducted and results will be shared with the participants, said Marnie Brown, R.N., study coordinator.

Volunteers will receive $250 compensation.

For further information, contact Brown at (415) 497-5266.

NURSING GROUP OFFERS PUBLIC LECTURES

STANFORD—

"Spanning the Ages, a three-part series of discussions focusing on health care needs required in childhood, adulthood and old age has been scheduled free for the public by the Stanford University Hospital (SUH) Friends of Nursing.

The first lecture, Wednesday, May 1, is entitled "Helping Your Child Deal with Life's Traumas." The program is a panel discussion featuring three registered nurses with advanced training. They are Janet Mohs, who works in the pediatric intensive care area; Pat Hartzer, a nursing education coordinator at Children's Hospital at Stanford; and Adrianne Burton, head of Child Life Services at UC San Francisco.

On May 8, Susan Zahl, nursing education coordinator at SUH, will discuss "Consumer Rights and Responsibilities in Today's Health Care System." On May 15, Karen Girton, a clinical nurse specialist in gerentology, will discuss the senior citizen years in her talk, "An Active Age."

All of the talks are scheduled from 7 to 9 p.m. in the Social Hall of the Community Congregational Church, 1985 Louis Road, Palo Alto. Friends of Nursing was founded in 1982 under the auspices of SUH to promote excellence in the visibility of nursing as a vital component of health care, and to support professional nursing practice at the medical center.

MEDICAL STUDENTS SPONSOR LECTURE BY POET PHYSICIAN

STANFORD—

About 35 Stanford University medical students have decided to bolster their ties with the humanities and have enlisted the aid of a physician/scholar recognized as a poet.

John Stone, professor of medicine and associate dean at Atlanta's Emory University is scheduled to discuss "The Patient as Art: When Physicians are Writers" at 8 p.m., Monday, May 6 in Fairchild Auditorium at Stanford Medical School.

The lecture, free and open to the public, is sponsored by the Stanford Medical Student Association and the members of the Humanities Study Group at the medical school, said Sylvia Cerel, a first-year medical student who has helped arrange the talk.

She said the humanities group, with about 35 members, is an effort to help students maintain intellectual, cultural and even emotional balance in their lives at a time in their studies when it is easy to become intellectually limited.

"Dr. Stone is an ideal speaker and wonderful role model because he is a full-time academic physician and is still very much a poet. I first knew him when I was a student at Emory, and it is amazing to see how fully integrated the physician and poet are," said Cerel.

"When he is talking to patients and when he is talking to poetry students, he uses the same voice. As a cardiologist he is acutely aware of rhythms, both with heartbeats and poetry," said Cerel.

Many of Stone's poems and prose concern medical topics and his reflections on life as seen from the perspective of a physician, Cerel said.

"You will not, I suggest, be able to properly manage the patient until you find the art within him," Stone wrote in a 1974 medical society article.

TRUSTEES APPROVE $1 MILLION HUMAN ANATOMY RENOVATION PROJECT

STANFORD—

A $1 million renovation project to improve facilities used for teaching gross human anatomy to medical students has been approved by the Stanford University Board of Trustees.

The project will provide seminar room space, improved cadaver storage, dissection rooms, laboratories and other program and code improvements, according to David Mendelow, associate dean for administration of the Stanford University School of Medicine.

Gross human anatomy, which teaches medical students basic human structure, is fundamental for physicians in every branch of medicine. The subject is taught in the Anatomy Building situated between Campus Drive and the Stanford Museum.

The space of 13,695 net square feet, presently occupied by the Human Anatomy Division, has been judged inadequate to support the academic program by both the Dean's Office and accrediting organizations, Mendelow said. And it must be in compliance with current safety code requirements. The building was constructed in 1892.

"A new facility is expected to be built in the next five or eight years to house human anatomy and other activities," Mendelow said. "While such a project is pending, some renovation of the existing space is necessary to support the teaching program and to bring the building in code compliance."

The renovation will be funded by the medical school's capital budget, Mendelow said, and the space should be available for the Autumn quarter.

BUDGET CUTS THREATEN U.S. COMPETITIVE POSITION IN FIELDS DEPENDENT ON SOPHISTICATED INSTRUMENTATION, PROFESSORS SAY

STANFORD—

Nine Stanford University professors, including three Nobel laureates, said Monday, April 29, that Reagan administration budget cuts will place the United States in a non-competitive position in fields dependent on sophisticated new instrumentation.

In letters to the appropriations subcomittees of the U.S. Senate and House of Representatives, the professors urged the Congress to restore support for biomedical research technology to the level originally mandated by Congress.

The signers included Nobel laureates Robert Hofstadter, physics; Linus Pauling and Henry Taube, chemistry. Reductions in the budget of the National Institutes of Health (NIH) and other cuts "constitute a major overall setback," the professors wrote. "However, especially alarming are the disproportionate and selective cuts in instrumentation programs."

In recent years Congress has received testimony from federal agencies and study groups that the United States is rapidly becoming non-competitive in fields of research that depend on instrumentation, the professors said.

Examples of the types of modern instrumentation regarded essential for rapid progress in medical science include computers, X ray equipment, million volt electron microscopes, synchrotron radiation and magnetic resonance facilities.

One report, published by the NIH, said:

"Research universities, which are responsible for conducting a critical share of the nation's biomedical research and training, are facing serious financial difficulties in replacing worn out and obsolete equipment and developing new instrumentation required for further research advances.

"Because these universities are responsible for training future investigators for science and industry, deficiencies in research equipment bode ill for future research in all settings."

The Congress responded by increasing the federal budget for instrumentation programs. But the Biomedical Research Technology Program of the NIH, for which the Congress had originally appropriated $43 million for fiscal 1985 has been cut back to $35 million by the Reagan administration.

"The administration's plan represents a major reversal and seriously impairs the ability of the NIH to meet crucial needs," the professors said.

"Continued progress and competitiveness in agriculture, industrial technology and health care critically depend on scientific innovation, and innovation increasingly depends on the use of modern technology."

Other letter signers are Arthur I. Bienenstock, professor of applied physics and material science engineering and director, Stanford Synchrotron Radiation Laboratory; Carl Djerassi, professor of chemistry; Edward A. Feigenbaum, professor of computer science; Oleg Jardetzky, professor of pharmacology and director Stanford Magnetic Resonance Laboratory; and Harden M. McConnell and John Ross, professors of chemistry.

DNA ANALYSIS EXPLAINS WHY "BUBBLE BOY" DIED, AND ADDS NEW INFORMATION ABOUT DISEASE IN IMMUNE DEFICIENT PATIENTS

STANFORD—

Stanford University scientists who studied tissues from Houston's "Bubble Boy" have confirmed that a viral infection resembling mononucleosis can evolve into a cancerous condition in patients with poorly functioning immune systems.

The finding, which explains what ultimately killed David the Bubble Boy, was made from an analysis of the youth's hereditary material, DNA, following his death.

The analysis revealed that David had abnormal cell proliferations as well as cancer in his lymphatic system, and that his diseased cells contained genetic material from a virus that causes infectious mononucleosis.

The findings about how David died could be significant for the medical management of other patients with suppressed immune function such as organ transplant patients who receive immunosuppressive drugs and those with David's disease—SCID (severe combined immunodeficiency), said Dr. Jeffrey Sklar, assistant professor of pathology at Stanford.

A report on the DNA analysis of David's tissues is scheduled for publication in the May 2 issue of the *New England Journal of Medicine*.

The article, which focuses on the last few months of the Bubble Boy's 12-year medical history, was written by 13 authors, including the Baylor College of Medicine physicians who cared for David, doctors from the University of Texas Health Sciences Center and from the Dana Farber Cancer Institute in Boston, and the team of Stanford University Medical School scientists.

The Stanford researchers who carried out the DNA work included Dr. Michael Cleary, a postdoctoral scholar in Sklar's lab, and Drs. Roger Warnke and Carl Grumet, both associate professors of pathology.

The members of the Baylor College of Medicine medical team that cared for David are Drs. William Shearer, Milton Finegold, I. Celine Guerra, Howard Rosenblatt, Dorothy Lewis, Marilyn Pollack, and Larry Taber, as well as Dr. Ciro Sumaya from the University of Texas Health Science Center at San Antonio. Dr. Jerome Ritz from the Dana Farber Cancer Institute prepared cells for David's bone marrow transplantation.

Sklar said that without the DNA analysis of David's tissues, it would have been difficult or impossible to answer some important questions about the boy's death. The fact that these questions were answered shows the range of current applications of molecular techniques to clinical diagnostic questions, he said.

David's condition—SCID—is a rare deficiency in which two types of white blood cells needed for defense against disease are absent or are present in very low numbers.

Doctors at Baylor College of Medicine kept the child in a "bubble" isolation chamber from birth to protect him against bacteria and viruses which could cause life-threatening infections in the absence of the body's normal immune defenses.

In 1983, David's doctors decided that a bone marrow transplant from his sister might bolster his deficient immune system sufficently to enable him to eventually leave his protective chamber. Bone marrow cells give rise to the cells that can defend the body against disease.

The doctors took marrow cells from his sister because her tissues were the closest match to David's own the doctors could find.

However, the transplant failed to boost David's immune function. Four months following the procedure, he died from cancer of the lymphatic system that had spread throughout his body.

The Stanford researchers analyzed David's DNA using molecular techniques to find out how his cancer arose.

They found that DNA from David's tumor cells contained genetic material from the Epstein-Barr virus, a virus known to be associated with disorders of the lymphatic system in immune deficient patients. The virus was probably transported into his body via his sister's bone marrow cells, the doctors deduced, since evidence for past viral infection was found in her blood, and David had never been exposed to the virus prior to the transplant.

The researchers also found that David's cancer arose from his own cells, rather than from cells transplanted from his sister.

In addition to malignant cell growths, they found that David's lymphatic system also had given rise to numerous non-malignant cell proliferations similar to those seen in viral diseases like mononucleosis.

Lymphatic disease is 40 to 50 times more likely to develop in immune deficient patients than in the general population, said Sklar, who together with Cleary and Warnke has studied the disease in Stanford's heart transplant patients taking immune suppressing drugs.

The occurrence of lymphoproliferative disease in transplant patients has spawned debate among medical researchers as to whether it develops as a virus infection in the manner of mononucleosis or as a primary cancerous process, Sklar said.

Some researchers believe the disease is a malignant lymphoma from the start while others view it as a viral disease, something like a "runaway" case of viral mononucleosis, Sklar explained.

In a study published last year, Cleary, Warnke and Sklar found that among a group of ten heart transplant patients with lymphatic disease, all had a cancerous form.

"But in David's case, we found both forms of the disease—malignant and benign—in one patient," Sklar said. Furthermore, the DNA in some of David's tumors suggested that the malignant clone of cells emerged from the benign form of lymphoproliferative disease.

"This provides good indirect evidence that lymphatic tumors can develop gradually over time from an unrestrained viral infection in immune deficient patients, probably caused by the Epstein-Barr virus," Sklar said.

The research methods the Stanford group used to analyze David's DNA included DNA hybridization, a way of measuring the degree of similarity between pieces of DNA. This enabled the scientists to find the evidence of Epstein-Barr virus infection in David, and also to tell that his cells, rather than his sister's cells, were the cancerous ones.

Another method called immunogenotyping, pioneered by Cleary and Sklar, enabled them to see that David had both cancerous and benign forms of lymphatic disease. The method relies on the fact that different lymphocytes in the body have slightly different arrangements of their DNA that can be used as identifying "fingerprints."

The researchers found several growths in which all the cells had identical fingerprints, a hallmark of cancer where a single cell goes awry, giving rise to identical daughter cells. But they also found proliferations of lymphocytes with different fingerprints, suggesting a condition more like mononucleosis.

Finally, Warnke analyzed David's tissues by a method called immunophenotyping, which examines antibody proteins produced by lymphatic cells. Results of these studies confirmed the DNA findings that both cancer and a mononucleosis-like condition were part of David's final illness, Sklar said.

NEW BLOOD TEST MAY HELP IDENTIFY PEOPLE WITH GENETIC SUSCEPTIBILITY TO ONE FORM OF ARTHRITIS

STANFORD—

Stanford scientists have developed a simple blood test that may help identify people who have a high genetic risk of developing one form of rheumatoid arthritis.

The new test also may speed up the diagnostic process for patients with this form of arthritis, making early treatment possible, the Stanford researchers said.

The test, which the researchers hope to make available for doctors' use in the form of a diagnostic kit, is undergoing evaluation for accuracy and effectiveness but is not likely to be commercially available until further studies can be completed, said Dr. Gary Fathman, associate professor of medicine at Stanford University Medical School.

In preliminary studies, the test has been able to identify 100 percent of patients diagnosed as having a particular form of rheumatoid arthritis called seropositive arthritis. But further testing on a larger number of patients is needed to establish the validity of the test, Fathman said.

The test is based on the fact that people with a high susceptibility to developing rheumatoid arthritis have certain genes in common.

These genes are located in a region of the human genetic material—DNA—known as the major histocompatibility complex (HLA).

The Stanford researchers have found a reliable method for using white blood cells to identify individuals whose DNA contains the "marker" genes.

Using the same principles on which the arthritis test is based, it might also be possible to develop diagnostic tests capable of identifying individuals genetically susceptible to developing juvenile diabetes and multiple sclerosis, Fathman said.

Fathman and his colleagues Drs. Kornelia Weyand and Jorg Goronzy, both postdoctoral scholars, reported on their research Tues., April 23 at a meeting of the Federation of American Societies for Experimental Biology in Anaheim.

"The major benefit of this test is that it would be a possible way of telling as early as prenatally if someone is susceptible to developing seropositive rheumatoid arthritis. Later, if they began experiencing arthritis symptoms, it would be possible to initiate treatment immediately for the best possible results," Fathman said.

With present methods, it may take as long as six months to make a diagnosis of arthritis after initial symptoms appear, Fathman explained.

The new test and others designed using the same principles also may enable doctors to identify subpopulations of arthritis sufferers for whom they can predict severity of disease and treatment outcome, Fathman said.

4/25/85

-more-

This would be of particular clinical benefit in rheumatoid arthritis because it is such a heterogeneous disease, Fathman said.

"There are some populations of arthritis patients who don't respond to the conventional therapy which yields disease remission in the majority," he said.

"Likewise, there are populations of patients with rheumatoid arthritis who have a very mild or benign course and don't need any major therapeutic intervention."

Knowing early on that a patient had a particular form of the disease would help doctors tailor design the best treatment, he said.

The test that Fathman and his colleagues have begun evaluating was designed to recognize seropositive juvenile rheumatoid arthritis, a very homogeneous form of the disease found in children.

In preliminary studies of a group of 23 adults who had classical arthritis symptoms and circulating rheumatoid factor—the conventional way of diagnosing seropositive rheumatoid arthritis—the test reacted with 100 percent of the patients, suggesting that their form of the disease is related to juvenile arthritis, Fathman said.

In a control group of 27 non-arthritic individuals, the test reacted with two, Fathman reported. The false positive results were not surprising, he added, since about 50 percent of people who are genetically susceptible to arthritis fail to contract the disease.

The test uses white blood cells, or lymphocytes, called T cells. T cells recognize proteins on the surface of other cells in the body.

Fathman and his colleagues isolated T cells that recognized an arthritis "marker" protein specified by one of the HLA genes, HLA-DR4.

Then by cloning, or growing in large numbers, these T cells from healthy volunteers, they obtained enough cells to make a diagnostic test possible.

Rheumatoid arthritis is thought to be an autoimmune disease. In some people, the body's natural immune response to a particular stimulus has an unfortunate side effect of destroying some of the body's own tissues, Fathman said. The HLA region of the DNA, which produces the marker proteins the T cell clones recognize, is involved in this immune response.

Multiple sclerosis and juvenile diabetes are also thought to be autoimmune diseases associated with HLA genes. In each of these diseases, distinct marker proteins are present in the body that could be recognized by T cells, Fathman said.

For this reason, it may be possible to develop diagnostic T cell clones for these diseases using techniques similar to those employed in the arthritis test, Fathman believes.

Stanford University is applying for a patent on the T cell clone technique, Fathman said.

The research was funded by grants from the National Institutes of Health and the Arthritis Foundation.

STANFORD MEDICAL STUDENT WINS COMMONWEALTH FUND FELLOWSHIP

STANFORD—

Monica de la Paz, a third year medical student at Stanford University School of Medicine, has been selected as a 1985 Commonwealth Fund Medical Fellow.

The Commonwealth Fund Fellowship Program is designed to encourage academically outstanding minority medical students to pursue career interests in academic medicine, said Leon Johnson, president of the National Medical Fellowships (NMF), Inc. of New York, which administers the program.

De la Paz, the only Hispanic selected for the honor, is one of 20 minority medical students from 14 institutions named fellows this year. In addition to de la Paz, the group of 12 men and eight women includes 18 Blacks and one student of Black and Puerto Rican parentage, the NMF said.

She will use the $5,000 fellowship to pursue research on coronary atherosclerosis risk factors with Dr. John Farquhar, director of Stanford's Center for Research in Disease Prevention, she said.

De la Paz, from El Paso, Texas, is interested in cardiovascular medicine. She said she hopes to learn more about medical research opportunities in that field, as well as about academic medicine in general, during her fellowship period with Farquhar.

WEIGHT LOSS SUMMER CAMP SCHEDULED

STANFORD—

Summer camps for teenagers and children who want to lose weight are being offered by the Stanford Laboratory for the Study of Behavioral Medicine.

Called SHAPE, the four- and eight-week programs are intended to teach weight loss through a balanced program of non-competitive exercise and healthful foods, said Keith E. Saylor, SHAPE co-director.

The eight-week program includes—in addition to traditional camp programs and weight loss assistance—instruction by professional male and female models in how to change image and wardrobe to fit a new self-image, Saylor said. He added this was the first time that modeling has been offered in the program's four-year history.

Four-week programs are held in two sessions, beginning June 24 and July 22. The eight-week program begins June 24. Groups are divided into 7 to 11 and 12 to 17 age groups. Costs range from $350 to $800, depending on age group and length of session, Saylor said.

The price includes appropriate meals and snacks, as well as parent seminars. Field trips to wilderness areas and a video aerobics tape are provided with the eight-week sessions, which range from three to four hours per day.

For further information, call (415) 497-5065.

WEIGHT MANAGEMENT PROGRAM SCHEDULED BY DIETETICS

STANFORD—

A 12-week course on weight management for teenagers has been scheduled this summer by the Stanford University Hospital Department of Dietetics, announced clinical nutritionist Kristine Birge.

Combining diet, exercise and behavioral techniques, the Shapedown Program is intended to help teenagers to take charge of their own weight management.

Classes for participants are scheduled from 3 to 4:30 p.m., June 11 through Aug. 27. Parent sessions have been scheduled at 7:30 p.m., on July 9 and Aug. 6

Cost for the program and materials is $165. The registration deadline is May 24. For more information call (415) 497-5432.

JOHNSON RE-ARRESTED FOR CHILD ABANDONMENT

STANFORD—

A woman mistakenly released from detention after being charged with abandoning her newborn baby was returned to custody Tuesday, April 23, after she walked into the Stanford campus police station.

"She wanted her belongings back," said Stanford Police Capt. Raoul Niemeyer. Betty Ann Johnson, 36, a transient from New York, was re-arrested on a Palo Alto Municipal Court warrant on charges of felony child abandonment, Niemeyer said.

He said the woman, who had been sought by police for nearly a week, returned to the campus sheriff's substation about 1:40 p.m. and inquired about some clothes and other possessions that were being held there following her first arrest.

Johnson was originally arrested by Stanford campus police April 16 after she allegedly left her newborn infant in the back of a pickup truck parked near Stanford University Medical Center. The baby girl, about four hours old, was taken to the center and then released to a foster home Saturday, April 20.

Officers said the child was born in a field on the campus where the mother reportedly had been camping for several weeks. Johnson was apprehended shortly after the baby was found, taken to the medical center for treatment and then transferred under arrest to the detention ward at Santa Clara Valley Medical Center.

Niemeyer said the woman was later transferred to the Elmwood Women's Detention Center but was released Thursday after officers failed to note that a warrant had been issued.

"Somebody basically goofed," Niemeyer said.

Niemeyer said the woman was processed at the sheriff's substation on campus and was expected to be transferred back to Elmwood later on Tuesday.

STANFORD UNIVERSITY HOSPITAL HEALTH FAIR:

THINGS TO SEE, THINGS TO DO, THINGS TO LEARN

STANFORD—

Free blood pressure tests, low-cost computerized health appraisals and information about Stanford University Hospital treatment programs, community services and ongoing projects will be offered at the health faire from 10 a.m. to 4 p.m. Saturday, May 4, at the Stanford Shopping Center.

The fair will also offer free blood glucose level tests, low-cost cardiac risk panel blood tests, information on medicare and health insurance programs and booths and exhibits on topics ranging from diabetes and cardiopulmonary resuscitation to normal and high risk pregnancy and Life Flight, the helicopter rescue program. The fair is open to the public.

Sponsored by the hospital's nursing department, the fair kicks off the annual nurse week. Activities include a May 8 lecture by Pamela Maraldo, R.N., executive director of the National League for Nursing and named one of 20 most successful women by *Savvy* Magazine. The week-long celebration will culminate with a 10K fun run through the Stanford University campus on May 12.

The health fair and nurse week theme is to "celebrate 25 years of caring and sharing." The activities are part of the medical center's 25th anniversary celebration, marking the move of the medical school from San Francisco to Stanford, which prompted the establishment of the medical center.

For more information about the health fair or nurse week activities, call Gaye Bruce or Joan Caldwell at 415-497-7261.

STANFORD EYE CLINIC ESTABLISHES LASER CENTER

STANFORD—

A new laser center for eye treatment has been established by the ophthalmology clinic at Stanford University Medical Center.

Located in newly remodeled space in the Boswell Building, the clinic has three new lasers. One of the lasers, a yellow Krypton laser, is one of only five in the world, said Dr. Michael Gaynon, assistant professor of ophthalmology.

"The yellow Krypton laser will set us apart from other laser centers," he predicted.

The rare yellow Krypton laser, a new argon laser, and a neodymium YAG laser were purchased with a $200,000 gift from the Televideo Foundation, established by Dr. and Mrs. Philip Hwang who also founded Televideo Corporation in Sunnyvale. Each type of laser has its own forte in ophthalmology, Gaynon said, and together they offer a wide range of treatment possibilities.

The beam of the yellow Krypton laser is much more precise than beams produced by other lasers, Gaynon explained, which may make it the laser of choice for many treatments. It has already been found to be more effective in treating the *macula lutea*, the section of the retina responsible for sharp focusing. Unlike the blue-green light produced by the argon laser, which is more easily absorbed by the central reading portion of the retina, the red and yellow light produced by the yellow Krypton laser is not, he explained. Thus, it has less chance of damaging healthy tissue.

The argon laser has been the mainstay of laser therapy in ophthalmology for many years, Gaynon said. The widely available machine is used to treat complications from diabetes, macular degeneration, retinal detachment, cateract corrections and other retinal vascular diseases.

"Lasers have really turned the tide for many patients who would have gone blind in the past," Gaynon said.

An estimated 75 percent of diabetics develop eye diseases, some of which can cause hemorrhage or detachment of the retina, the light-sensitive tissue lining the back of the eye. Even those diabetics who are not as severely affected often develop leakage from abnormal capillaries, sometimes suffering severe loss of vision. By using the argon laser, ophthalmologists can cauterize the leaky vessels or weld the retina back onto the eye. At the very least, Gaynon explained, this often allows them to stabilize their patients' vision; sometimes they can even improve it.

4-23-85

-more-

The elderly often lose reading vision because of little blood vessels that grow abnormally and bleed underneath the retina. The laser can cauterize these errant vessels and preserve patients' vision. And in patients who have retinal tears—about two out of every 100 among those who have had cataracts removed—the laser can weld the tear to keep the retina from detaching.

Ophthalmologists are using lasers more and more to treat glaucoma, a disease that can cause blindness, especially in people over 40 years old. The condition is caused by blockage of normal fluid seepage out of the eye, which prompts the pressure to increase until it damages the entire eye. By using lasers, physicians "irrigate" the eye, restoring the pressure back to the normal range. Until now, this could only be done surgically.

The YAG laser, on the other hand, emits an invisible infrared light. Unlike the argon laser that works by heat, the Yag laser creates very precice and controlled microexplosions that literally blow up the tissue, Gaynon explained. Though still considered experimental by the Food and Drug Administration, the YAG laser is now used along with surgery on about 10 percent of the 500,000 cataracts removed each year.

Laser stands for Light Amplification by Stimulated Emission of Radiation. It involves either a gas, liquid or solid. The argon laser, for example, is basically a glass tube with mirrors at each end. The tube emits coherent precisely directed, powerful beams of light consisting of one or more colors. The type of gas or other substance in the laser tube determines the color emitted, which determines what what type of tissue will absorb the light as well as how penetrating that light will be.

A plaque-hanging ceremony honoring the Televideo Foundation for its gift of the funds for the purchase of the lasers, is scheduled for 5 p.m., April 26, in the clinic.

The lasers are just one type of treatment available at the clinic, with its new treatment rooms, waiting areas and reorganized operation.

"The new clinic will allow us to see patients in a much more timely and comfortable fashion," said Dr. Michael Marmor, associate professor of ophthalmology and head of the ophthalmology division.

For information or to schedule an appointment, call 415-497-6995.

STANFORD SCIENTISTS STUDY PROTEIN LINKED TO NERVE REGENERATION

STANFORD—

Stanford University neurobiologists are reporting new work on a protein that appears to be linked to the regrowth of damaged nerves in mammals.

Their findings could help scientists begin to understand at the molecular level why mammalian nerves in the brain and spinal cord cannot regrow after injury.

Dr. Hans Werner Muller, Dr. Peter Gebicke-Harter, Donald Hangen, and Dr. Eric Shooter are publishing a report on the protein in the April 26 issue of *Science* magazine.

The protein, initially discovered by Dr. Pate Skene, assistant professor of neurobiology, and Shooter, has been found in newborn rats and in rats with damaged nerves.

It may play a role in nerve growth in the young animals and in nerve repair in the injured adult rats, said Shooter, who is professor and chairman in the department of neurobiology at Stanford University School of Medicine.

Although it is only a basic scientific discovery with no medical applications now, the finding is a small step in the effort toward developing a treatment for spinal cord injuries and other currently irreversible conditions caused by damage to brain and spinal cord nerves, Shooter said.

He explained that in mammals, injuries to the peripheral nerves—such as those in the limbs or skin—can be repaired because axons, the long fibers of nerve cells, are capable of growing back to reform the pathways originally established during development.

But for some reason, damaged nerves of the brain and spinal cord do not regrow, Shooter explained. This is why spinal cord injuries, head traumas, and other conditions involving injury to the brain or spinal cord are so severe and irreversible, he added.

The scientists found in rats that a specific protein associated with growing nerves is synthesized at a high rate early in development when nerves are first being formed. Later in life, when the nervous system is established, the protein's synthesis drops off to a much lower rate.

But if the nerves are damaged, then adult rats synthesize the protein at high rates again both in the peripheral nerves and in the central nervous system, Shooter said.

The protein accumulates in the peripheral nerves, which regrow to repair the damage, Shooter explained, and once these axons have regrown, the protein's synthesis falls to low levels again.

But despite the fact that it is also synthesized in the central nervous system, the protein does not accumulate around damaged brain and spinal cord nerves.

"The lack of accumulation of the protein in the adult mammalian central nervous system may represent one of the critical molecular differences between peripheral nervous system and central nervous system which limit the ability of central axons in mammals to regenerate," the scientists wrote.

Shooter said that it is not yet known what role the protein might play in nerve regeneration. His lab is currently studying the protein's structure and function, and where its synthesis occurs.

Preliminary results suggest that the protein is not only manufactured by cells in the nervous system but also by cells in the blood that migrate to the site of injury.

The research was supported by funds from the National Institutes of Health and the Isabelle Niemela Estate.

EXPANDING CLINICAL PRACTICE NOT AN ANSWER TO MEDICAL SCHOOL FINANCIAL WOES, STUDY SHOWS

STANFORD—

Increasing the patient care load of full-time medical faculty to offset lost research revenue will "probably fail and undermine present research activities," a Stanford University School of Medicine study shows.

"Research, essential to improving health care, cannot expect substantial support from other faculty activities," concluded the authors in the April 18 issue of *The New England Journal of Medicine*.

"Academic medical centers, which derive their financial basis from research support, should consider very carefully the effects before attempting to expand their clinical practices," said Dr. Kenneth Melmon, professor of medicine.

The study, conducted by Drs. Melmon, David Chin and Halsted Holman of Stanford's department of medicine, and David Hopkins, director of analysis and planning for the medical center, looked at the activities of Department of Medicine faculty members for a one-year period in an attempt to correlate them with sources of revenue.

The study was funded by the Robert Wood Johnson Foundation Clinical Scholar Program and the Kaiser Family Foundation.

The study shows for the first time, Holman said, that full-time faculty members typically spend about one-third of their time involved with research, one-third with patient care and one-third with teaching and administrative duties. The key issue for academic medical departments, Holman continued, is whether the array of activities should be maintained, and how they should be financially sustained.

"Subsidizing research activities with income from clinical activities won't work," Holman said.

Departments of medicine are typically the largest in academic medical centers. Stanford's department, with nearly $16 million in research revenue, includes 11 divisions plus the Stanford Center for Research in Disease Prevention.

The study looked at faculty members' activities during the year of 1980. Faculty members were observed for 40 of the 62 hours that made up the average work week. Faculty members reported their own activities for the remainder of the time. Activities were categorized into "patient care," "research," "teaching," and others. The largest percentage of activities—a minimum of 60 percent—were reported as "joint products," meaning that the activity fell into more than one category. Hospital rounds, for example, may fulfill patient care and teaching roles, and possibly research roles as well.

-more-

Each full-time faculty member devoted to research activities brought an average of $944,000 to the department through direct and indirect research awards, the study showed. In comparison, faculty members devoted to the highest revenue-producing specialty—cardiology—produced only $507,000 in patient-care charges. The actual reimbursement from insurance companies and other third party payers was expected to be less.

It would take as many as 15 non-procedure-oriented full-time faculty members, the authors surmised, or as few as eight procedure-oriented full-time faculty members to produce the same amount of research support as one research-oriented full-time faculty member.

"The pressures academic medical center administrators think they're feeling to place more emphasis on clinical practice may not be entirely accurate," Melmon said.

Not only would an increased emphasis on clinical practice cut into research support, the authors stated, it would also cut back on the amount of time available to faculty members to devote to research.

And, they added, "recent trends in health-care financing and local competition from a growing supply of physicians severely limit the expansion of clinical activities that might generate excess revenues."

Five other medical school departments of medicine have since conducted similar studies, Melmon said, all with differing results.

"An attempt to find a blanket solution will not work," Melmon said. "Each school must be considered individually."

The authors state multiple reasons for the decline in research and patient care revenue.

* Many departments were developed through research funding during the emergence of modern biomedicine and are now experiencing a decrease in federal research support due to inflation and competition from increased numbers of schools and faculty.
* Steeply rising costs of health care are causing reimbursement agencies to restrict payments.
* Intensive specialization in medical departments has heightened dependence on referral patients.
* Competition for patients is growing from the increasing numbers of physicians in private practice.

NEWBORN BABY ABANDONED IN HOSPITAL PARKING LOT; MOTHER FACES CHARGES

STANFORD—

A 37-year-old transient from New York City was arrested Tuesday shortly after her healthy newborn baby was found in the back of a pickup truck in a Stanford University Hospital employee parking lot.

The baby girl was taken to the hospital for observation where she was reported in excellent condition about 12:30 p.m., said Kathleen Palange, a clinical nursing coordinator. Palange said the baby was about four hours old and its placenta was still attached when brought to the hospital.

The woman, identified as Betty Ann Johnson, was apprehended at the Hoover Pavilion annex to Stanford Hospital, several hundred yards from the truck where employees had discovered the baby about 10:45 a.m., said Stanford Police Capt. Marvin Moore. The woman was to be booked Tuesday for investigation of felony child abandonment, Moore said. The truck was owned by a construction worker on the hospital modernization project, said hospital security supervisor Wayne Beban.

The woman was taken in police custody to the hospital emergency department, where she was reported in stable condition. Mary Durando, an emergency department supervisor, said the woman required stitches to close tearing which occurred during delivery.

Moore said the mother was found after a witness described a woman who had rapidly exited the parking area where the baby was found. Durando said the woman had told officers that she had come to California from New York via Florida and had found refuge by camping in the woods for at least several weeks near the mausoleum on the Stanford campus.

Moore said Santa Clara County Child Protective Services had been contacted. Palange said in cases of abandonment, newborn children are ordinarily placed in protective hold, which allows the hospital to provide care.

Carol Jensen Vaughn, a hospital office assistant, said she was summoned to the employee parking lot at 10:30 a.m. across from her office on Welch Road by "two women who came over and asked for help."

Vaughn said she called hospital security and then followed the women to the pickup truck, where they saw the baby wrapped in what appeared to be drapery. The infant, she said, was placed on newspapers in a cardboard box. Hospital security dispatched an ambulance and then contacted the campus substation of the sheriff's office.

11 COMPANIES SIGN ON WHILE FOUR TERMINATE LICENSING AGREEMENT WITH STANFORD

STANFORD—

Stanford University's genetic engineering licensing program has signed up eleven new companies since last August when the second of two major gene cloning patents was issued, a university official said.

During the same period, four companies terminated the licensing program, said Niels Reimers, director of the university's office of technology licensing.

This makes a total of 73 companies now licensed to use the patented recombinant DNA technology that underlies the entire biotechnology industry, Reimers said.

The new sign-ups are Merck and Co., Becton Dickinson, Phillips Petroleum, BASF, California Biotechnology, Calgene, Genencor, Life Technologies, Syntro, ZymoGenetics, and Triton Biosciences, a division of Shell Oil Co., said Katharine Ku, associate director of technology licensing.

The companies that terminated are Cetus, a biotechnology firm based in Emeryville, Universal Oil Products, an energy/engineering company, Carter-Wallace, a health care company and Koppers, a chemical company, Ku said.

The most notable drop-out company is Cetus, which has two biotechnology products—human beta interferon and human interleukin-2—nearing marketability, Ku said.

In a letter to Stanford stating the reasons for Cetus' decision, the company's patent attorney said, "it is our opinion that Cetus' existing and prospective activities are not included within the scope of any valid claim of either patent...and therefore it is no longer necessary or appropriate to maintain the license agreement."

"Cetus' termination is a disappointment," Reimers said. He added that the university is presently evaluating the Cetus withdrawal with regard to potential future action.

No litigation concerning the patents has been initiated, Reimers said. But he did acknowledge that some funds have been put aside should legal proceedings occur. The university is also consulting with Washington, D.C. patent attorney Donald Dunner on potential legal actions concerning the patents.

Stanford's genetic engineering licensing program is based on two patents covering gene cloning techniques, and the recombinant molecules produced through these techniques, developed by Stanley Cohen of Stanford and Herbert Boyer of the University of California, San Francisco (UCSF).

The two patent applications were filed in 1974. The "process" patent issued in 1980 and the "products" patent issued in 1984.

Although Stanford handled the patent applications and administers the licensing program, the two universities share revenues accrued through the program, Reimers said.

Over $3.5 million have been received since the licensing program was initiated in 1981, Ku said.

Terms of the licensing agreement call for a sign-up royalty plus an annual $10,000 minimum royalty in addition to earned royalties on sales.

4-15-85

-more-

The earned royalty rate for end products is one percent on net sales ranging up to $5 million, three-quarters of one percent on sales between $5 and $10 million and one-half of one percent on sales above $10 million annually. (Separate royalty rates apply to bulk products, basic genetic products, and process improvement products).

Companies that signed up before Dec. 15, 1981 received the most favorable terms in applying the sign-up and basic annual royalties as credit against earned royalties, Ku said.

At least ten companies now have reportable sales, Ku said. Most of the products that have become available using the patented techniques are scientific research products, Ku said.

Only one pharmaceutical product is on the market, she added, a form of human insulin called "Humulin" developed by Genentech and marketed by Eli Lilly.

In addition to the Cetus products, several other pharmaceutical products are nearing commercial availability, including a hepatitis B vaccine, human growth hormone, and a drug for treating emphysema, Ku said.

Following is a list of the licensees as of April 12, 1985:

Abbott Laboratories
Advanced Genetic Sciences
Agrigenetics
Ajinomoto
Allied Corporation
American Cyanamid
American Home Products
Austgen-Biojet Int'l.
BASF Aktiengesellschaft
Baxter-Travenol
Becton Dickinson
Bio Logicals
Biogen, N.V.
BioTechnica International
Boehringer Mannheim GMBH
Bristol-Myers Company
Burroughs Wellcome
Calgene
California Biotechnology
Celltech Limited
Chiron Corporation
Codon
Collaborative Research
Corning Glass Works
CPC International
Creative Biomolecules
DNA Plant Technology
Du Pont
Eli Lilly
Engenics
G.D. Searle
Genencor
Genentech
Genetics Institute
Genex Corporation
Gist-Brocades N.V.
Green Cross
Hoechst AG
Hoffmann-La Roche
Integrated Genetics
International Mineral and Chemical
Johnson & Johnson
Kyowa Hakko Kogo
Life Technologies (GIBCO/BRL
Merck
Microlife Genetics
Miles Laboratories
Mochida Pharmaceutical
Molecular Genetics
Monsanto Company
Montedison S.p.A.
Nabisco Brands
National Distillers and Chemicals
New England Biolabs
Novo Industri A/S
P-L Biochemicals
Pfizer
Phillips Petroleum
Repligen Corporation
Revlon
Salsbury Laboratories
Schering AG
Schering Corporation
SmithKline-Beckman
Stauffer Chemical
Suntory
Synergen Associates
Syntro
Takeda Chemical Industries
Triton Biosciences
Upjohn
W.R. Grace
Zymogenetics.

STANFORD'S YOUNGEST TRANSPLANT PATIENT RETURNS HOME

STANFORD—

Elizabeth Craze's joy at tricycle riding and jumping down the stairs belie the nearly two-decade odyssey of fatal disease which has afflicted her family.

The youngster was only 2 1/2 last Oct. 8 when she became Stanford's youngest heart transplant patient. On Saturday, her parents were scheduled to take their bouncy daughter back home to Cleveland, where she will be reunited with her 18-year-old brother, Andrew.

He received his own heart transplant July 10, 1983, and returned to school the following fall. Now he is doing well enough to return to Stanford next fall—this time as a computer science freshman.

Andrew and Elizabeth are the fortunate children of Charles and Susan Craze. The couple's oldest son and a set of twins all died of the same disease which triggered Elizabeth and Andrew's transplants.

"We certainly have high hopes that Elizabeth will do extremely well and have a long lifespan," said Dr. Sharon Hunt, the Stanford cardiologist who takes care of transplant patients after surgery. "We've set no limits as to her physical activity."

Hunt said familial cardiomyopathy is essentially a deterioration of the heart muscle. The condition is rare, and even rarer as an inherited condition. While the cause is uncertain, Hunt said a current theory is that some people inherit an almost fatal sensitivity to a virus which is harmless to most people.

Cardiomyopathy has accounted for nearly half of the 335 transplants at Stanford since January 1968. Other than experimental drug treatments which offer promise, transplantation has been the major treatment for the condition in its advanced stages. The other most common reason for transplantation, coronary artery disease, occurs more often and can be treated in a variety of ways.

Elizabeth had been diagnosed as having cardiomyopathy when she was 1 month old, "but she was doing well and we had no sense of urgency" until last summer when she came out with her brother for his annual checkup, her mother said. Her condition had deteriorated. Doctors agreed to accept her into the program, which has been cautious about accepting young children, whose ability to deal with a complicated drug regimen during their growth years is uncertain.

Still Stanford's youngest transplant patient, Elizabeth's robust health so far is encouraging for future pediatric transplants, Hunt said. the child's surgeon, Dr. Philip E. Oyer, said he was pleased with her progress so far. "She looks wonderful. When you see her you would never think she has had a transplant," he said.

Hunt said she expects that the donor heart will grow along with Elizabeth, whose weight of 31 pounds is slightly small but not abnormal for a 3-year-old.

-more-

Charles Craze, 44, a constitutional lawyer, and Susan Craze, 42, have been anxious to maintain family privacy since they rented a house near Stanford to be near their daughter before and after transplantation. But on the eve of their return to Cleveland, they both agreed to share their story in hopes that the public will be aware of the need for heart donors.

"We know of one case back in Cleveland," said Susan Craze, "where a family was willing to donate a heart of their child because they knew Andy and realized how much could be gained."

The Crazes can tell details of their story calmly, but not dispassionately.

In August 1967—four months before the world's first heart transplant operation took place in South Africa—the Craze's first child, Charles Jr., called Cheddy, died at 19 months of cardiomyopathy.

In 1968 the Craze's were given false hope of a happy family life when Susan gave birth to twin girls, Megan and Caitlin. Both children also came down with familial cardiomyopathy, which killed Megan in October 1971. Caitlin held out a bit longer but died in June 1972, the mother said.

Andrew was barely beyond the toddler stage when his twin sisters died, but the family was hopeful through the boy's healthy childhood that he might be free of the frequently fatal disease. Andrew remained healthy until Memorial Day in 1983, when for the first time he complained of chest pains toward the end of his sophomore year in high school.

His condition had developed so rapidly, that Susan Craze estimated that he only had a few weeks to live when a donor was found for him at Stanford where he had been waiting.

Charles Craze, recalling the loss of his own children, said he felt doctors shouldn't be reluctant to raise the possibility of organ donation to the relatives of a brain dead individual.

"Physicians need to understand that they need to give people credit for the ability to cope with grief. They should not be too reluctant to ask that life be passed on to someone who can benefit."

As Craze spoke during an interview, Elizabeth repeatedly jumped down from a bench, apparently restless to return home to Cleveland. For the past few months she has lived with her family, making occasional visits to Stanford's outpatient cardiovascular clinic.

"We know how it feels to lose children," said Susan Craze. "But if people can look past their grieving, offering the organs of a loved one has to be one of the most unselfish things they can consider."

Marguerite Brown, donor coordinator for the heart transplant program, said the news conference scheduled Friday (April 12) was intended as the prelude to national Donor Awareness Week April 21-27, an educational effort intended to make the U.S. public aware of the need to carry donor permission cards or allow a family members' organs to be used for transplanation.

Many persons who could benefit from a kidney, heart or other organ die before an appropriate donor is found. In the Stanford program alone, Hunt said about one potential recipient in four dies before a heart donor is found.

"A lot of our effort is public awareness," said Brown. "If more people could see healthy young people like Elizabeth and Andy Craze, they would realize just how much good can come from a decision to donate organs.

INTRAVENOUS FEEDING IS SAFE FOR MOST PREGNANT MOTHERS AND THEIR INFANTS

STANFORD—

Pregnant women who are undernourished because of an underlying medical problem can safely be given adequate nutrition intravenously, say doctors at Stanford University and the University of Southern California (USC).

In a study published in the April 12 issue of the *Journal of the American Medical Association*, the doctors reported that ten women who were fed intravenously during pregnancy delivered healthy normal birth-weight infants and experienced no obstetrical or fetal complications attributable to the intravenous feedings.

These findings help demonstrate that nutrient formulas are safe, when necessary, for pregnant mothers in the second and third trimesters and their children, said Dr. Kent Ueland, professor and acting chairman of gynecology and obstetrics at Stanford Medical School.

Ueland published the study with Drs. David Seifer and Valerian Catanzarite of Stanford and Santa Clara Valley Medical Center in San Jose, and Drs. Howard Silberman, Chris Conteas, and Robert Wood from USC and the Los Angeles County-USC Medical Center in Los Angeles.

Intravenous nutritional therapy has been consistently shown to be beneficial in nearly all patient groups studied, the doctors reported.

But a special consideration in obstetrical patients is whether the components of standard nutrient formulations produce unique adverse effects on either the mother or fetus, they added.

The ten women had a variety of illnesses that prevented them from digesting or absorbing enough nutritious food through the digestive tract. Their medical problems included conditions such as severe nausea and vomiting associated with pregnancy, bowel obstruction, and gall bladder inflammation.

One patient was treated during the first trimeseter, three during the second trimester, and five patients in the third trimester of pregnancy. Another patient received therapy during both the second and third trimesters.

Ueland stressed that more studies are needed to determine the safety of intravenous nutritional therapy during the first trimester.

The doctors noted that inadequate nutrition during pregnancy is associated with increased risk to the infant, including low birth weight.

STANFORD UNIVERSITY HOSPITAL SHARES 'INNOVATIVE' SOLUTIONS TO NON-MEDICAL HEALTH CARE PROBLEMS

STANFORD—

How do you talk with patients who don't speak English? Have volunteers who speak foreign languages to serve as translators.

How do you help out financially-strapped patients and families coming from out-of-town for treatment who need housing? Rent them apartments for $10 per night.

If these solutions sound simple, they are deceivingly so. The problems are representative of the hundreds of non-medical issues that can impact medical care that health care professionals and hospitals at Stanford University Medical Center and all over the country face every day. The solutions to them and other problems are included in the "1985 Innovators Catalog" published by Healthwest Foundation's *Hospital Forum*.

Stanford's hospital has several solutions to problems included in the catalog, illustrating the innovative and imaginative nature of the institution's management, said Jeanne Kennedy, director of the office of community and patient relations. The entries and people to contact for more information follow:

- *Home project*—To lessen the financial burden for out-of-town patients who must find short-term housing in a high-cost area, the Assistance League of Santa Clara County and the hospital now provide a low-cost housing program to patients coming from outside a 50-mile radius. The League rents and manages five one-bedroom apartments near the hospital. Plans are under way to expand the program.

  Contact Jeanne Kennedy, 415-497-7167.

- *Translator Bank*—To allow communication between non-English speaking patients and physicians, nurses and other personnel, foreign language-speaking volunteers were recruited to serve as interpreters. More than 80 translators with proficiency in 23 languages participate in the program. They are available on an on-call basis.

  Contact Sharon Beckham, coordinator of volunteer services, 415-497-7424.

- *Physician-nurse committee*—To promote a more cooperative, effective working relationship between nurses and physicians, monthly meetings were established to serve as an opportunity to discuss and resolve shared problems. More than seven groups exist and those who participate notice increased tension and misunderstandings on units where such groups do not exist.

  Contact Ann Baldwin, nurse consultant, 415-497-5100.

- *Care review-risk management*—To define and monitor quality care on an ongoing basis, hospital personnel were assigned to run four programs constituting a hospital-wide system of care review: quality assurance, risk management, infection control and utilization reveiw. Administrators, physicians and nurses are involved in each of the programs. Through them individual patient care can be assessed and long-term institutional plans can be made.

  Contact Karen Axnick, director of care review-risk management, 415-497-6824.

- *Clinical microbiology data base/diagnostic related groups (DRG) analysis data base*—To establish inexpensive, flexible methods of collecting and analyzing data for these programs and others, low-cost microcomputer systems were installed that substitute for a major portion of use of larger computers. Costs were reduced and use of computers and data was simplified.

  Contact Kevin Volkmann, manager of microcomputer program, 415-497-7691.

KICKOFF EVENT SCHEDULED FOR STANFORD HOSPITAL MODERNIZATION

STANFORD—

Surrounded by a jazz band, 2,000 balloons, and a display of construction equipment, an estimated 1,000 persons are expected to attend formal kickoff ceremonies April 10 for Stanford University Hospital's modernization project.

The public event, from 4 to 6 p.m. at the hospital construction site, is intended to show both members of the Stanford and neighboring communities what work has already been started and to emphasize the commitment that is needed by the university, hospital and neighboring communities, said Paul Edwards, associate director of medical development.

While the hospital's highly specialized care has attracted patients from many countries, SUH statistics show that more than 80 percent of the 23,572 annual admissions come from the Bay Area.

"Stanford University Hospital is indeed the link that binds us together, whether or not we consider ourselves 'Stanford people' in any other sense," said Stanford President Donald Kennedy.

"We are making a $112 million commitment for modernization at a time when health care needs are changing so rapidly that the future survival of many present hospitals is seriously in doubt. It is by any yardstick a bold move, one which anticipates our future health care needs, and expresses confidence in our society's commitment to meet those needs," Kennedy said.

Besides Kennedy, speakers at the ceremonies are to include Palo Alto Mayor Leland Levy, as well as hospital executive vice president and director Sheldon King, and Lawrence G. Crowley, vice president for medical affairs. The Stanford Jazz Band, attired in overalls and hard hats, is scheduled to perform before and after the speeches, held at the construction site near the corner of Blake Wilbur Drive and Quarry Road.

The modernization project, which includes renovation as well as new construction, is expected to be completed by December 1987. Kennedy has said the modernization project will provide 20 new operating rooms and two new four-story wings of patient beds. While no beds are being added to the current total of 663, the project will allow an increase in the average square foot per bed from 891 to 1,387, near the average for teaching hospitals throughout the country.

The ceremony, said Crowley, formally marks the kickoff of a public appeal intended to raise $15 million of the total cost from the business community and private donors. Additional money was expected to be raised through the issue in December of $81.6 million in bonds.

Nearly $1 million of the fundraising total, said Crowley, has already been raised from pledges by area corporations, including Hewlett-Packard Co., Varian Associates, Pacific Gas and Electric Co., Syntex Corp., Apple Computer Inc., Saga Corp., Lane Publishing Co., Advance Micro Devices Inc. (AMD), TAB Products Co., California Water Service Co., Lucky Stores Inc., Fairchild Camera and Instrument Corp., Siltec Corp., Industrial Indemnity Co., Del Monte Corp., and Teledyne MEC.

RADIATION HELPS SEVERE ARTHRITIS AND LUPUS

STANFORD—

Patients with previously untreatable rheumatoid arthritis have obtained long-term relief from stiffness and pain following treatment with a form of radiation therapy developed by Stanford University doctors.

This form of radiation therapy—called total lymphoid irradiation (TLI)—also shows promise as a treatment for severe lupus nephritis, a disease in which the immune system attacks the kidneys, the doctors reported.

The potential of TLI against the two diseases was outlined in two reports published in the April issue of the *Annals of Internal Medicine* by Dr. Samuel Strober, professor of medicine at Stanford University School of Medicine, and his colleagues, including Dr. Richard Hoppe, associate professor of radiology.

The reports suggest that TLI, a radiation treatment developed more than two decades ago for cancer patients, may now be finding a niche as a treatment for some autoimmune diseases, conditions in which the immune system turns against the body's own tissues.

In rheumatoid arthritis, which is estimated to afflict nearly two million people in the U.S. alone, the immune system is believed to attack the joints. The kidneys are one of the main autoimmune targets in patients with lupus, who are estimated to number a few hundred thousand, Strober said.

TLI's action against these diseases probably stems from its ability to suppress part of the immune system, Strober said.

The radiation treatment—which consists of 2,000 rads delivered over a six-week period—appears to be more effective against severe arthritis and lupus than the conventional drugs used to treat these diseases, Strober said.

In addition, its relatively benign side effects make it preferable to more powerful cytotoxic (cell-killing) drugs with undesirable side effects, which are now used as last resort treatments for both conditions, he said.

Strober's colleagues in the arthritis study are Drs. Amir Tanay, Elizabeth Field, Richard Hoppe, Andrei Calin, Edgar Engleman, Brian Kotzin (Veterans Adminstration Medical Center, Denver), Byron Brown, and the late Henry Kaplan.

Collaborators in the lupus study are Drs. Field, Hoppe, Kotzin, Engleman, Ovadia Shemesh, Jon Ross, and Bryan Myers.

Nine of 12 patients with advanced rheumatoid arthritis who received a moderate dose of TLI (2,000 rads) showed significant improvement in morning stiffness and joint tenderness six months after therapy. Three patients improved in a control group of 11 given a low dose of TLI (200 rads), Strober and his colleagues reported.

After six months, the eight control patients who had not improved were given moderate doses of TLI and six then also improved, Strober said.

All the patients had previously failed to improve with conventional anti-arthritic drugs such as gold compounds, penicillamine, and aspirin-like anti-inflammatory agents, the scientists said.

Although many patients who entered the study had lost the ability to care for themselves or to carry out normal household or occupational duties, those who improved following TLI frequently regained the capacity to work, or to feed, clothe and bathe themselves, the scientists said.

In a separate study, eight of 10 patients with lupus who had failed previous forms of therapy—anti-inflammatory agents and cytotoxic drugs—showed substantially improved kidney function for at least one year following the radiation treatment, Strober said, and some patients have maintained the improvement for almost four years.

-more-

Although a high proportion of patients with severe lupus nephritis eventually require kidney dialysis, none of the TLI patients needed dialysis in four years of followup, Strober pointed out.

Usual symptoms of lupus, such as skin rash, headache, chest pain, fever, and fatigue, have been minimal or undetectable in these patients, Strober said. Some patients also recovered from a disabling accumulation of many pounds of excess fluid, he added.

Among the lupus patients who improved, the turnaround came despite a worsening of their disease for at least six months prior to entering the study, Strober said.

The improvement after TLI enabled nine of the 10 lupus patients previously given cytotoxic drug therapy to eliminate these drugs and to reduce by almost one-half their daily dose of prednisone, an anti-inflammatory agent, he added.

But Strober said that despite the promising results from both studies, it is still too soon to know whether TLI should be routinely considered as a treatment for patients with intractable arthritis or lupus.

Although benefits have continued for as long as four years in some arthritis patients given TLI in an earlier pilot study, follow-up for five to ten years, with close monitoring of long term side effects, will be necessary to firmly establish when to use TLI in treating rheumatoid arthritis, Strober said.

The lupus results are more preliminary, he added, since the study was only a pilot program—rather than a controlled trial—to test the feasibility of using TLI in lupus patients.

Side effects observed among the patients were less severe than those that can be caused by cytotoxic drugs, Strober pointed out.

Both groups of patients experienced temporary side effects from the radiation, such as nausea, loss of appetite and fatigue, none of which persisted more than two months, Strober said.

Some patients later developed viral infections, which were treated with antiviral medication, and some experienced a drop in certain blood components, he added.

TLI is a form of therapy in which radiation from a linear accelerator is aimed at lymph nodes throughout the body.

It was developed in the 1950s by the late Dr. Henry S. Kaplan of Stanford, as a treatment for patients with Hodgkin's disease, a cancer of the lymphatic system.

During the radiation treatment, non-lymphoid tissues in the body are shielded by lead barriers while radiation is focused on lymph nodes of the neck, chest, and abdomen, and on the thymus gland and spleen.

TLI causes a drop in the number of lymphocytes, white blood cells responsible for the body's immune response, including the defense against infection. Yet, less than one percent of the Hodgkin's patients treated with TLI contract severe bacterial infections requiring hospitalization.

In addition, none of the several hundred cancer patients treated with high dose radiation in this manner over the past 10 years has developed leukemia, and none of the arthritis and lupus patients has developed a malignancy as a result of the radiotherapy, Strober said.

Autoimmune diseases are thought to be caused by an abnormality of one type of T lymphocyte—a suppressor lymphocyte—which plays an important role in keeping the immune system in balance.

Suppressor cells are like the brakes of the immune system; without their inhibiting action a runaway effect can take place in which the defense system's destructive cells attack some of the body's own tissues.

TLI, which causes a long-lasting drop in the overall number of lymphocytes, actually increases the relative proportion of suppressor cells, Strober and his colleagues discovered.

TLI also appears to encourage production of a cell called a natural suppressor, which helps the body tolerate transplants of foreign tissue. For this reason, Strober and his colleagues have also been testing TLI's ability to help kidney transplant patients avoid rejection of the new organ.

Last year, the scientists reported that TLI enables kidney transplant patients to survive with only minimal drug therapy, sparing them from the adverse effects of potent anti-rejection medications.

The arthritis research was supported by grants from the KROC Foundation. The lupus research was funded by grants from the National Institutes of Health.

SMASH LECTURES FOR THE SPRING

STANFORD—

The Spring 1985 S * M * A * S * H (Stanford Medical and Scientific Highlights) lecture series at the Stanford University School of Medicine begins April 12.

The lectures, open to the University and medical community, will be held in the Fairchild Auditorium, at 4:30 p.m.

All lectures are designed to present current frontiers of bio-medical investigation in a manner that everyone with a basic scientific background will be able to understand.

The season's lectures are:

- April 12: "Cell Recognition During Neuronal Development," Dr. Corey Goodman, associate professor of biological sciences;
- April 26: "Social Cells and Intercellular Communication," Dr. Dale Kaiser, professor of biochemistry;
- May 24: "T Cell Clones and Ir Genes," Dr. Garrison Fathman, associate professor of medicine (immunology).

The lecture series was initiated in 1980 by the medical school's Faculty Senate, which now cosponsors it with the Stanford Medical Students Association.

AUXILIARY BOASTS 25 YEARS OF SERVICE

Photos available on request if not included with story.

STANFORD—

In honor of its 25th anniversary, the Stanford University Medical Center Auxiliary was given a special reception in March by the board of directors and administration of Stanford University Hospital.

The Auxiliary is a non-profit volunteer organization which had its beginning in 1929 and took its present form in 1959 when the medical school moved from San Francisco to the university campus.

Today's Auxiliary, an in-hospital service organization, has nearly 600 members, and directs the services of several hundred active volunteers. Auxiliary members have contributed more than 1.7 million hours of service to the hospital, working on more than 15 different services.

Originally a small group formed in support of the old Peninsula Hospital in Palo Alto, the Auxiliary at that time had as its primary purpose the raising of funds for needy patients in the community.

The Auxiliary now donates many of the funds it raises through the gift shop and baby photo sales, together with contributions, to services and equipment that help patients directly. To date, financial donations by the group exceed $1,300,000.

Ruth Allen, a member for 15 years, said Auxiliary programs have not changed much, but that the hospital, just like everywhere, is depending more on volunteer help these days for many different kinds of work that used to be affordable. She sees that trend as one of many changes that have occurred at the hospital since she joined the Auxiliary.

One of the most important new activities, Allen feels, in terms of its benefit to the community, is Lifeline. The program began just over a year ago, providing an emergency link to the hospital for geriatric, chronically ill, and cardiac patients.

Sharon Beckham, coordinator of volunteer services at Stanford Hospital, said, "I don't think the motivations for volunteering have changed that much over the past 25 years. There is still altruism, but I think too more people today are interested in specific assignments to gain certain skills.

"Just as society has seen more women entering the work force, current trends have impacted volunteerism in the United States," she said. "There are fewer 'traditional volunteers' today than there were 25 years ago. There are more working people, younger people, career-oriented people, and men are volunteering too.

"Those members who joined the Auxiliary initially were a very special group, representing a valuable resource that is fast diminishing," Beckham said.

Carol Davis has been with the Auxiliary since its incorporation in 1959, focusing primarily on the gift shop. But the aspect of the job she likes most, she said, is "seeing a smile on a sick patient's face."

Most members would agree. "I found I had a special rapport with patients and families," said Allen, recalling how she first joined the group. "Working with patients is my love—that's when I really feel I'm doing something useful."

Davis is one of several Auxiliary members who have been with the group the whole 25 years of its existence. They were honored at the recent reception, along with all members of the Auxiliary.

Among awards presented at the reception was a plaque given to the outgoing Auxiliary president, Donnie Ellington. Phyllis Alper, incoming president for 1985-86, was welcomed.

HOSPITAL INTERPRETERS SERVE AS MENTORS IN PROFESSIONAL PROGRAM

STANFORD—

Stanford University Hospital's four Spanish-language translators will be serving as mentors in a new college program this summer intended to train students for the specialized skill of helping hospital patients who do not speak English.

Under terms of a May 8 contract, about 25 students at the Monterey Institute of International Studies will be spending one-week internships with one of SUH's four interpreters, said Wilbur Wright, director of the clinical social work service which directs the translator program.

In addition, at least two of the translators—John Chavez and Gisela Pyka—will visit the Monterey school for up to three weeks to lecture language students about the specifics of translating in a medical setting.

The contract, signed for Stanford by Director and Executive Vice President Sheldon S. King, should provide an opportunity to help develop an important new profession, Wright said.

Herschel Peak, a spokesman for the 450-student school, said the three-week certification program is limited this year to its own students in two-year master's degree programs. When the program is repeated in following summers, Peak said the school hopes to include non-student bilingual workers in the three-week course.

Chavez said officials at Monterey sought out Stanford's interpreter/translators because the program, started here 14 years ago, has gained a widespread reputation and has been largely unduplicated at other institutions. (Stanford's original sole interpreter, Olga Guerra, recently became a clinical social worker, Wright said.)

"The lack of a formal training and certification program for translator/interpreters is something else that we're trying to change through a formal association we helped form, the American Medical Language Services Network. We have developed a code of ethics and are in the process of developing a formal certification process for translators (who translate written material) and interpreters (who deal with the spoken word)," Chavez said.

Other institutions cooperating in the network include, Santa Clara Valley Medical Center in San Jose, Highlands Hospital in Oakland, the Department of Health and Human Services Office of Civil Rights, and the San Francisco Health Department.

Stanford's four interpreter/translators will be assisted by interns from Monterey on a full range of duties, which include interpreting physician queries to patients about their health, translating prescription directions and instructions for patients, as well as discussions between health professionals and patients and their families.

5-30-85

-more-

Chavez said the hospital and the Monterey school are attempting to fill a specialized need for interpreters and translators who are knowledgeable about medical terminology and sensitive to the cultural needs of foreign language speaking individuals in a medical setting.

For example, Chavez noted that knowledge of medical terminology in two languages is needed before someone can accurately translate symptoms and biological terms during a physician exam.

Also, the translators can serve as a resource to health care professionals here by alerting personnel to cultural sensitivities of patients which might differ from routine practice. For example, Pyka noted that families in many Latin cultures are less likely to be candid about life threatening conditions.

"The interpreter can explain the cultural feelings of the patient to the doctor, who may or may not insist on the patient's right to know." Ultimately, the interpreter complies with the physician's wishes, "but we feel our input contributes to the final answer," she said.

Chavez said it is crucial to use well-trained professionals to avoid the pitfalls which can occur when other bilingual hospital personnel are used informally as interpreters.

He said precise language skills and technical knowledge is needed to translate biological terms and information accurately.

"And we need to ensure that people in our profession adhere to a strict code of ethics. The translator/interpreter must be sensitive to cultural values and suggest when something might be stated differently. But ultimately we are responsible for conveying the health professional's message. The last thing you need in a health situation is for a translator arbitrarily to impose values by altering what the doctor is saying."

As an example, Chavez recalled a case at another hospital where a housekeeper, instead of translating a doctor's recommendation that a patient undergo surgery, advised the patient against an operation.

Hospitals, said Chavez, also face the risk of losing malpractice or discrimination suits if they fail to use qualified translators. Hospitals also face the risk of losing federal fundings if they fail to adhere to maintain proper standards by providing needed language services.

"Our people here at Stanford spearheaded a new profession," said Wright. The four interpreter/translators currently work primarily in Spanish and English because of the high volume of need among primarily Spanish-speaking patients and families. About 20 percent of Stanford's aproximately 23,000 patients speak Spanish as a primary language and many of these people require translator services, Wright said.

The hospital Office of Community and Patient Relations maintains a volunteer translator pool for other languages which works closely with the four regular Spanish translator/interpreters, Chavez said.

The Monterey program will include persons with primary language skills in such other languages as Russian, German, Japanese and French, said Pyka.

Wright said Chavez and Pyka were selected to give the initial lectures in Monterey because they both have advanced degrees and have lectured for Monterey Institute students in the past. Pyka, from Chile, is working on a Ph.D. in physiology at Stanford, while Chavez is a doctoral candidate in early childhood education at the University of California at Berkeley.

Stanford's other interpreters, who will be involved in the mentor program, are Josefina Fayard, from Mexico, and Eva Wasmer, a UC Berkeley graduate who grew up in the United States in a household where her Nicaraguan parents spoke Spanish.

JOYCE LAWSON: THE "PROTOTYPIC TECH" OF RADIATION THERAPY

STANFORD—

It's a typically hectic morning in the radiation therapy department in the basement of Stanford University Hospital. Quick smiles and occasional inquiries of "How are you?" among staff go unanswered as they focus their attentions on patients, spilling over into the cramped reception area from the waiting room filled with spouses, children and friends. Like a busy freeway junction, technicians, physicians, nurses and patients walk by and around each other with no collisions, amazingly enough, to reach their destinations.

An older gentleman shuffles in carrying a pink bakery box tied with string. "You're going to make us fat," says the tall, thin chief radiation therapy technologist, Joyce Lawson, with a faintly discernible Scottish lilt revealing of her origin. "We missed you on Friday," she adds, pointedly waiting for an answer.

"He was on a drinking binge and was too embarrassed to come in for treatment," she later explains, munching one of the doughnuts the box contained. "There's a strong correlation between the combination of smoking and alcohol among patients with head and neck cancer. When they find out they have the cancer, they often drink more to escape reality. But how can you get mad at them? If you're told you have a life-threatening disease, that's when you rely on your crutch the most.

"You get to know patients pretty well," Lawson continues. "They come for treatment every day for six weeks at a time. During that time the physicians usually only see them once a week. You're their primary contact; you're the one who sees their emotional ups and downs."

Lawson has seen thousands of ups and downs during her 40 years as a radiation therapy technician, administering high-powered radioactive beams to thousands of patients suffering from cancer. Nearly 30 of those years have been at Stanford, where she was hired by the late Dr. Henry Kaplan to operate the first medical linear accelerator in 1955 and has contributed to the radiation therapy department's international prominence.

"She's probably been treating patients longer than any other human being," says Dr. Malcolm Bagshaw, chairman of the radiology department. "There are not many radiation therapy technicians who are known, but a lot of people know who Joyce Lawson is."

"She's the prototypic tech," adds radiologist Dr. Norman Coleman. "She's conscientious; she's interested in delivering high quality radiation; she's a real professional."

And the profession is Lawson. During her years at Stanford she has molded the radiation therapy department and the other technicians to meet her high—and strict—standards. She has held onto as much of the physical area as she's been able to, but in the spatial crunch of the hospital, the department has been squeezed into a small area she doesn't like nor think is entirely workable. She's taken out her frustrations, however, by consulting in the planning of other institutions' departments and by developing "quite nice" plans for the new department in the hospital modernization project.

Lawson started a radiation therapy technician school in 1962, training more than 100 techs until the school merged in 1982 with one at Foothill Community College. The students still come to Stanford as part of their coursework. "We get to see who the good ones are so we can hire them,"she says matter-of-factly.

"They get things here they don't get elsewhere," Lawson says, such as Wednesday afternoon conferences when physicians, residents, nurses and techs discuss each patient currently under their care. "I encourage them to go so they can learn about the diseases and treatments and also so they can get an overall picture of each patient.

"I nurture the attitude that each patient should be treated as an individual and not just as patient X. It's the patient contact that keeps me going in this job. We try to make treatment a personal, positive experience. Anybody who doesn't think that way doesn't belong in radiation therapy. The last thing patients need is a cold shoulder."

This congenial, sympathetic attitude may seem a bit odd to some colleagues, who diplomatically figure if they haven't got anything nice to say about Lawson, they won't say anything at all. Yet none dispute her skill as a tech, and many look up to her as a role model. "She can fly through anything," Coleman acknowledges.

"She's strong-willed and outspoken," Bagshaw admits. "But she's dealing in an area where the stakes are incredibly high. She tends to be a bit strict with residents and other techs, but they think she's terrific. She brings techs here, whips them into shape and then everybody can't wait to steal them."

"I've got a file drawer full of letters from patients praising Joyce and the other techs for the confident and friendly way they were treated," Bagshaw reveals. "Joyce is responsible for any compliments we get."

"You have to tread a narrow path between getting too involved in a personal way and yet being involved enough so the patients are aware that you really are genuinely interested in them and in their problems," Lawson explains during a breather, her legs sprawling as she relaxes in a chair in her tiny office filled with books and travel memorabilia.

"Patients seem to open up to us more than to the physicians," she continues. "Lots of times they'll hesitate to ask questions; they don't think the physicians have the time or they don't want to seem stupid. We give out a lot of basic information and explanations of exactly what's happening to them."

What the therapy actually does inside the patients' bodies can be hard to comprehend, Lawson says. Depending on the area to be radiated, patients are precisely situated in either a reclining or sitting position under one of the ominous-looking machines. The experience is somewhat like that of being X-rayed; the patients don't feel anything as the powerful beams penetrate their bodies. Reactions to the treatment—nausea, diarrhea, swollen glands, for example—surface later.

"Sometimes cancer patients will say to you 'I don't think I'm going to make it. Why are we doing this?' " Lawson says. "You *have* to say to them 'We're doing everything we can. We can't give any guarantees but you've got to do everything you can too. We've got to work together.'

"We know some of the patients aren't going to make it," she says, "but even so you can really make their remaining time a lot more comfortable."

Radiation therapy is a far cry from languages, Lawson's true interest during her school years in her native Scotland. But when she was graduating from high school, the British army was drafting women. Since radiation therapy was one occupation that would keep her out of the war, she decided she'd rather switch than fight.

-more-

After World War II ended, Lawson emigrated to Canada to work with the first cobalt 60 irradiation unit, a breakthrough in deep-penetrating radiation treatment. "I worked my tail off there," she recalls. "The doctors used to go home at 5 p.m. and leave me there until 11 treating patients."

That went on until one day her roommate suggested she look for a job in California, the vogue thing to do among Canadian nurses in those days. She wrote to the chief radiologist at University of California, San Francisco, who replied that a young radiologist, Henry Kaplan, at Stanford was interested in hiring her.

"I'd never heard of Stanford," Lawson says. But the prospect of operating the newest technological invention intrigued her, and the rest, as they say, is history.

"We moved down here in 1959 when they built the hospital," she continues. "We started treating people before they even had the linoleum laid. We were walking around in all this goopy black stuff and the workmen were still building and painting around us."

In the years since the move, the one linear accelerator has been replaced by three—a fourth is on its way—and Lawson has seen the field of radiation therapy develop. "We've pioneered many of the techniques here. We've had a few key people and the equipment to make some real contributions to the field. Bagshaw, with his advances in prostate cancer, is keen on trying new and innovative ways of doing things. And of course Kaplan, with his success with Hodgkin's patients, was a man of such enormous intellect—he was on to so many things."

"The physicians are the ones who get the credit for contributions to radiation therapy," Bagshaw says, "but the suggestions on how to do things better have come from everyone, including Joyce."

The high energy linear accelerator is the end of the technology line, Lawson believes. Future advances in radiation therapy lie in the combination of radiation and adjunct treatments, such as those involving chemicals and temperature changes, that increase the sensitivity of cancerous tumors to radiation.

Lawson herself did not go unscathed. She developed thyroid cancer about 18 years ago, which was treated and successfully cured. "I'm sure I got it from the early work with radiation before we knew the exposure to it was harmful," she says. "I panicked at the initial shock of being told I had cancer, but then I realized it was a very treatable kind. But I did develop a new sense of empathy for patients because I experienced what cancer was like.

"But then I have patients who I treated 20 years ago coming to visit and they're all right. That's the type of feedback that keeps me going," she adds.

Lawson paid a visit of her own recently. About a year ago she visited the Smithsonian in Washington, D.C., where the first linear accelerator now stands as a museum piece. "I went down and said hello," she says. "I feel like I grew up with that machine. I felt like I was visiting an old friend."

FIRST STEP TOWARD A TEST TO IDENTIFY DIABETIC PATIENTS AT RISK FOR COMPLICATIONS

STANFORD—

A new finding that may pave the way toward early diagnosis of diabetic patients who are likely to develop certain severe complications of the disease, has been reported by Stanford University researchers.

In an article in the May 30 *New England Journal of Medicine* the scientists report that most diabetic patients with kidney disease, visual problems, or nerve damage have high levels of a certain substance in their blood.

Healthy individuals and diabetics without these complications have much lower blood levels of the substance, called prorenin, said Dr. John Luetscher, professor of medicine (emeritus) at Stanford University School of Medicine.

The complications—which are called "microvascular" because they are caused by changes in the body's small blood vessels—do not arise in every patient who has diabetes, but when they appear, their effect can be very destructive, leading to partial blindness, kidney failure, or pain, the researchers said.

Estimates are that between 20 and 30 percent of diabetic patients develop at least some of these problems over the course of 10 to 20 years, Luetscher said.

The new finding opens up the possibility of using blood prorenin levels to spot susceptible diabetic patients early in the course of the disease before their complications become irreversible.

"If we have a test that can identify patients at risk, then we can make more efficient use of modern technological advances to treat the disease," Luetscher said.

His colleagues in the research are Dr. Fredric Kraemer, assistant professor of medicine and head of Stanford's adult diabetes clinic, Dr. Darrell Wilson, assistant professor of pediatrics and head of the diabetes clinic at the Children's Hospital at Stanford, Dr. Herbert Schwartz, professor of pediatrics, and Dr. Michael Bryer-Ash, senior resident in medicine.

Although most physicians believe that careful control of blood sugar levels may help reduce the incidence and severity of microvascular complications, "lack of compliance by large numbers of diabetics makes current practice relatively ineffective," Luetscher explained.

But if a patient knew he was at high risk of developing serious complications, he would probably be more likely to take measures to control the disease, such as following a careful diet, controlling blood sugar levels, or taking insulin, Luetscher said.

5/29/85

-more-

In addition, susceptible patients could benefit from new treatments as they become available for diabetes, he added.

However, the researchers stressed that it is too early to say conclusively that prorenin levels accurately predict those at risk.

"This study shows that patients who develop microvascular complications consistently have high prorenin levels, while those who escape complications usually have normal levels of prorenin. But it will take several years of monitoring patients to ascertain whether an increased prorenin level can actually predict the appearance of these complications," Luetscher said.

The researchers are studying a promising new drug called glipizide, which can reduce high levels of prorenin in diabetics.

"But again, it will take time to determine whether this agent can postpone or prevent the appearance of complications," Luetscher noted.

Prorenin is an inactive form of an important body hormone called renin that is produced in the kidneys and helps regulate blood vessel function and the body's water balance.

Normally, prorenin is converted to renin in the kidneys. One possible explanation for higher blood prorenin levels in patients with microvascular complications is that the kidneys become damaged in some way so that they cannot convert the inactive prorenin substance into renin, the researchers suggested.

The kidneys are highly sensitive to microvascular changes, they noted, so it is not surprising that early signs of complications would alter their function.

MORAL JUDGMENTS ON RESEARCH DEBATED AT AAAS MEETING

STANFORD—

Stanford's Committee on Research has reaffirmed the university's basic policies on freedom of inquiry at a time when the defense department is looking for more participation by the nation's universities in military-related research, David Korn, dean of Stanford's School of Medicine told the scientific community Monday, May 27.

The committee upheld Stanford's policy that funding for research on campus must be based solely on the scholarly merit of the work and not on any moral judgements about possible outcomes of the research, Korn told a workshop at the annual meeting of the American Association for the Advancement of Science, being held in Los Angeles this week.

The Stanford committee, which Korn chairs, also voted last year to continue to prohibit Stanford scientists from conducting any classified or secret research.

The workshop, titled "Military Research and the University: Questions of Responsibility," dealt with the issue of how universities can balance academic freedom for their faculty with institutional obligations to society.

There is a long history, in this country and in Britain, of cooperation—and mistrust—between the military and university scientists, said George Gamota, who directs the Institute for Science and Technology at the University of Michigan in Ann Arbor. And the ambivalent relationship between the military and universities is exemplified by the longstanding dilemma of whether the University of California should continue to manage the national weapons laboratories at Los Alamos and Livermore, said Willie Fraser, Vice President of Academic Affairs for the UC systems, another participant in the workshop.

Currently, the defense department is pressing for more university involvement in research that would aid national security. According to Gamota, the U.S. Senate has asked for an appropriation of $25 million to fund defense department efforts to solicit more grant proposals from university researchers. The House wants to greatly increase the appropriation to $175 million.

The exact amount, which would be included in the 1986 budget, is now being debated by a conference committee, Gamota said.

Korn related how a clash developed two years ago between two national laboratories situated on the Stanford campus, the Stanford Linear Accelerator Laboratory (SLAC) and the Stanford Synchrotron Radiation Laboratory.

Both labs are funded primarily by the Department of Energy, and each lab conducts research independently of the other. Yet the synchrotron facility must obtain its synchrotron x-rays from SLAC.

The clash came in 1983, when the synchrotron lab began a new set of research projects that included work for testing and calibration of nuclear detectors. The project was unclassified, with no restrictions on the dissemination of the research results. Some SLAC researchers, however, including faculty, staff, and

students, protested that research dealing with nuclear weaponry was "categorically inappropriate" for a university setting, Korn said. And "because SLAC had to produce the x-rays required for (synchrotron) research many of the SLAC researchers felt co-opted into participating in research that was morally repugnant to them."

The synchrotron research had been funded because it met the Stanford criteria: peer review judged it to be sound science, and it was not classified. Yet dissension among the researchers involved provoked Stanford's faculty senate to ask the Committee on Research to re-examine Stanford policies on academic freedom, Korn said.

The committee locked into a heated debate. A minority held that Stanford should adopt a prohibition against research whose future applications could prove harmful to society. Such a restriction, they argued, had a precedent in the existing ban on secret research, and in limits on research with human subjects.

The majority, however, took the view that moral judgements cannot be used to restrict university research. "Such judgements tend to reflect an individual's satisfaction with social, political, and ethical values, or with government policies, which change with time and circumstances," Korn said.

He noted the committee did debate scenarios where research goals might be "clearly heinous"—such as research to develop poison gas for mass extermination of people. But the committee members could not come up with useful generalizations that would guide decisions on all research topics. "We couldn't put it into words," Korn said.

Meanwhile, the University of Michigan, in addition to a policy forbidding classified work, has adopted a ban on any research whose "clearly forseeable end is to destroy human life or incapacitate humans," said Gordon Kane, a professor of physics at the Ann Arbor campus.

Korn worries that such a restriction could interfere with research in areas such as diagnosing malformations in unborn humans, which, because of the abortion debate, is a sensitive topic.

But Kane says of the University of Michigan's decision, "we felt it was better to err on the side of caution."

COMMUNITY HEALTH EDUCATION CONFERENCE PLANNED

STANFORD—

Stopping disease before it starts through community education is the focus of a July 24-26 conference for health professionals sponsored by the Stanford Center for Research in Disease Prevention (SCRDP).

William Haskell, associate director of SCRDP, said the conference, "Health Promotion and Disease Prevention in the Community," will feature lectures and workshops conducted by a variety of nationally recognized guest and Stanford authorities. Sessions will include material on both conceptual and practical issues of successfully achieving chronic disease prevention through community-wide health education, he said.

Lectures range from such theoretical discussions as "Application of social learning theory to community health programs" by Albert Bandura, professor of psychology at Stanford, to practical sessions such as "Use of contests for health promotion," conducted by June Flora, director of education for SCRDP, and Mia Clark, SCRDP special events coordinator.

Among the 32 faculty members are such guest lecturers as Lester Breslow, dean emeritus and professor of public health at the UCLA School of Public Health; Donald Iverson, associate director of the Cancer Control Science Program, Division of Cancer Prevention and Control, National Cancer Institute; J. Michael McGinnis, deputy assistant secretary of Health, director of the Office of Disease Prevention and Health Promotion for the Department of Health and Human Services; and Elaine Stone, health scientist administrator, National Heart Lung and Blood Institute.

SCRDP, which includes the Stanford Heart Disease Prevention Program, has been involved with community health education through its Five Cities Project and other community-based health efforts for more than a decade.

The conference is open to health profesionals interested in the theory and practice of community health education, including physicians, health educators, health counselors, nurses, dietetians, public health personnel, volunteer health organziatoin staff and private health program administrators.

For further information, contact Edelen Stevens, (415) 497-6254. Credit is available for physicians and nurses from the California Medical Association and for appropriate registrants from the American College of Sports Medicine.

EYE, HEART AILMENTS TARGETED BY FUND FROM FORMER STANFORD PRESIDENT

STANFORD—

More than $1.1 million from the estates of Stanford University's fourth President and his wife will go to the School of Medicine for the study of glaucoma and other eye, as well as heart, diseases.

Donald Tresidder had heart disease, and his wife, Mary, suffered from glaucoma.

The university board of trustees authorized the use of the funds for such research on Monday, May 13.

Both Donald and Mary Tresidder were graduates of Stanford, and devoted a great part of their lives to serving the university.

Donald Tresidder served as Stanford University president from 1943 until his death in 1948. In 1934, he helped found the Stanford Associates, a fund raising group. He was named to the Board of Trustees in 1939.

Before assuming the university presidency, Donald Tresidder was president of the Yosemite Park and Curry Co. at Yosemite National Park, a vacation-resort concession established by his wife's family.

In 1970, Mrs. Tresidder established by bequest the Donald B. and Mary C. Tresidder Charitable Remainder Annuity Trust Fund, which paid income for life to two beneficiaries. The last beneficiary died in January, making the principal of the trust available to the School of Medicine.

As of December 31, 1985, the principal of the trust will be more than $1.1 million, according to the Committee on Academic Affairs and Development, which made the recommendation to the trustees.

MALPRACTICE REFORM MUST COME FROM OUTSIDE MEDICINE

STANFORD—

Reform to alleviate both the size and increasing frequency of malpractice suits against physicians must come from outside the medical system, Dr. David Rubsamen told a Stanford Medical Alumni Association Symposium Saturday, May 18.

"As malpractice insurance premiums skyrocket because of the large awards granted to plaintiffs by the courts, the answer may be found in some type of state mechanism for insuring doctors," he said.

Physicians can play a role in educating California lawmakers about the seriousness of the problem, he added.

Rubsamen, an alumnus with both medical and law degrees from Stanford, is editor of the "Professional Liability Newsletter" which comments on current legal-medical decisions and how they affect California physicians.

Since 1968 malpractice verdicts in the state against physicians have sharply increased in size and frequency, Rubsamen said, with multimillion dollar awards constituting the most alarming trend, he said.

Several developments account for this, Rubsamen said. They include a greater willingness among patients to sue their doctors, and the number of attorneys spawned by law schools. Their numbers in the past 15 years have jumped from 2.9 attorneys per 100 physicians to 11 per 100. The best of the trial attorneys are attracted to the goldfields of malpractice litigation. And the public cannot help but be impressed by the million-dollar verdicts.

"But the most single outstanding feature is that physicians for the first time have been willing to testify against other doctors," he said.

This trend has had its roots in today's higher standards of medical practice and medicine's ability to respond rapidly to physiological events through sophisticated techniques and equipment.

"Fifteen years ago even the most catastrophically injured patient would have been lucky to win as much as $500,000," he said. "And in most instances such cases were not even tried."

One example is the field of anesthesia, Rubsamen said. A series of "anesthesia disasters" was reaching the courts in the late sixties and early seventies, resulting in large awards. For awhile it seemed unlikely that anesthesiologists would be insurable against malpractice. But the doctor-owned insurance carriers imposed on them new requirements and standards. The measures have reduced litigation incidence by 15 percent.

-more-

5-20-85

Another vulnerable specialty is obstetrics and gynecology. Its problem stems from technical advances to salvage newborns which previously would have died. The most common suits involve brain damage often caused by a combination of human error and machine failures in labor rooms and neonatal ICUs.

"The problem is so serious," Rubsamen said, "that ob-gyn specialists may become uninsurable in the next four to five years."

Perinatal damages can be reduced significantly if high technology services were concentrated in metropolitan hospitals only, he said.

The passage of the Medical Insurance Reform Act, which became law in 1975, has had beneficial effects, Rubsamen noted. The law placed limitations on attorney fees in malpractice cases and required disclosure of plaintiffs' collateral benefits from other sources, pensions, insurance etc. The California Supreme Court last February put a quarter-million cap on the amount victims may collect for pain and suffering by malpracticing physicians, a provision knitted in the 1975 law.

"These measures have encouraged lower settlements and more fair verdicts," Rubsamen said.

Communication with the public is important in reducing the incidence of medical malpractice suits, Rubsamen feels. In teaching hospitals, for instance, it's not sufficient to say that the resident is "on the team" working with the faculty member. The patient must be made aware the resident will be performing the operation.

"A hospital's legal responsibilities can be relieved by a policy of complete disclosure, which has been the method used in the Stanford surgery service for years," he said.

Ideally, the best approach for dealing with medical malpractice is arbitration, he said. This would eliminate the jurors and courtroom. Arbitration would be informal with a hearing in a small office instead of the courtroom with an arbitrator agreed upon by both parties. The approach is similar to that used in tax cases.

The no-fault system, advocated by some, is another option, but it would bring pressures for defensive medicine far in excess of anything present today, Rubsamen said. In a no-fault system compensation means payment for every unanticipated liability. No-fault deals only with cause, and the issue of negligence does not arise.

In theory such a system would define "a standard of perfection for medical care" and paying compensation to any patient who suffered damages for lack of it, he said.

NEW GENE TECHNIQUE AIDS SEARCH FOR TUBERCULOSIS, LEPROSY VACCINES

STANFORD—

Scientists at three institutions said Monday, May 20 that they are using a powerful new gene isolation technique to help identify new vaccines against two diseases that may afflict 50 million people worldwide.

The new biochemical approach has enabled the researchers—based principally at Stanford University School of Medicine, the Whitehead Institute for Biomedical Research, and Albert Einstein College of Medicine—to identify protein fragments that they hope to develop into vaccines against tuberculosis and leprosy, said Dr. Ronald Davis, Stanford professor of biochemistry.

The new vaccine-hunting strategy was originally developed by Dr. Richard Young—formerly a postdoctoral scholar with Davis and now at the Whitehead Institute and Massachusetts Institute of Technology—and Davis as a powerful tool for isolating genes in basic biological research.

"But what may originally have looked like an arcane research tool has turned out to have enormous practical value," said Dr. Barry R. Bloom, professor of microbiology and immunology at Albert Einstein College of Medicine, who is a collaborator on the tuberculosis and leprosy work.

A report on the tuberculosis vaccine research was published in the May issue of the *Proceedings of the National Academy of Sciences*.

Other collaborators include Dr. Clemens M. Grosskinsky of Albert Einstein College of Medicine, and Dr. Juraj Ivanyi, from the Wellcome Research Laboratories in England.

The leprosy work is being carried out by Young, Bloom, Davis, and Drs. Vijay Mehra and Douglas Sweetser at the Whitehead Institute and MIT, Dr. Thomas Buchanan of the University of Washington, and Dr. Josephine Clark-Curtis from Washington University.

The research is funded by the World Health Organization and the National Institutes of Health.

The new technique has broad potential for the field of vaccine development because until now, researchers generally needed considerable knowledge about a disease-causing organism in order to find even one possible vaccine against it, Young said.

The new strategy, based on recombinant DNA techniques, bypasses that need, Young said. It can search for and find all potential vaccine proteins at once for a given disease-causing organism, even if researchers have little knowledge of how the organism causes disease or if the organism can't be grown in culture, he explained.

But he added that while the new technology streamlines the search for potential vaccines, these promising vaccine candidates must still be developed into a form that can be delivered to people, and they must be tested in the normal way for safety and effectiveness in carefully controlled studies before being used on a wide scale.

This testing phase could become speedier as well, because of the new technology's capacity for isolating, and therefore, cloning the gene that codes for each vaccine candidate, Young said.

(A vaccine is a weakened disease-causing microorganism or protein material from the microbe that can be administered to stimulate the body's natural defenses against disease.)

The scientists chose leprosy as one of their first vaccine targets because the bacterium that causes the disease cannot be grown in the test tube, stymying attempts to develop an effective vaccine against it, Bloom said. The bacterium that causes tuberculosis is closely related to the leprosy pathogen but easier to work with, he added.

"In this country people have forgotten about these diseases," Bloom said. Yet tuberculosis is a respiratory infection that is estimated to afflict 30 million people worldwide and to kill 3 million annually, he added. Although there is a vaccine available for tuberculosis, recent studies in Asia suggest that it is not very effective, Young said.

Leprosy, thought to affect 10 to 15 million people worldwide, is re-emerging as a major world health problem as resistance to antibiotics develops in the bacteria that cause the disease, Davis said.

A recently developed vaccine against leprosy is showing preliminary promising results, Young said, but it needs to be made from the bacterium that causes the disease, which can only be grown in the laboratory in armadillos. "This is expensive and virtually impossible to do in large enough quantities for worldwide use," Young pointed out.

The new technology not only allows researchers to spot each protein or protein fragment that has vaccine potential but also permits isolation of the gene that directs production of the protein, Young explained.

By isolating these genes and using genetic engineering techniques, the researchers expect the vaccine candidates can be produced in large quantities, first for testing and later on a large scale for worldwide use if they are proven effective.

Young said that it is too early to predict when human testing might begin. The researchers are currently trying to modify an existing live tuberculosis vaccine with the genes they have isolated.

The workhorse of the new gene isolation technique is a special type of virus developed by Davis and Young, called lambda gt11.

Scientists dissect the genetic material, DNA, of a disease-causing microorganism into its individual genes, and splice these genes into lambda gt11's DNA. The virus serves as a ferry, carrying single genes into E. coli bacteria.

Hundreds of thousands of bacterial colonies are grown, each a tiny factory with a specialized output of only one particular protein from the disease-causing organism under study.

The proteins manufactured by each bacterial colony are then screened with antibodies against the disease to find proteins with vaccine potential. Since there are so many bacterial colonies, each producing a different protein from the disease-causing organism, the researchers believe the procedure won't miss any proteins of interest, Young said.

The technique is so powerful that it would even detect "silent" genes, those that code for proteins rarely produced by the organism or produced only during active infection, Davis said.

The new strategy also allows scientists in many laboratories around the world to isolate genes and proteins for more basic biological studies, Davis said. For the first time it gives researchers the ability to isolate any gene if they have an antibody to the protein specified by the gene, he explained.

The new biotechnology method can also be used to develop more sensitive and effective ways to diagnose infectious diseases. For example, some closely related strains of disease-causing organisms could be distinguished from each other if each produced unique proteins. The new method would allow researchers to find these unique proteins, Davis said.

(Davis can be reached at (415) 497-6277; Young can be reached at (617) 258-5218; Bloom can be reached at (212) 430-2889.

MODERATE ALCOHOL USE INCREASES BLOOD PROTEIN LINKED TO REDUCING HEART ATTACK RISK

STANFORD—

Moderate alcohol consumption may reduce the risk of heart attacks by increasing a blood protein which has been linked to reduced risk of heart disease, according to a study by Stanford University researchers.

However, clinical physicians and researchers at the Stanford center where the 14-week study was conducted warned that alcohol consumption, particularly for motorists and pregnant women, poses other well established risks which must be weighed against potential benefits to the heart.

"We certainly don't recommend that people who normally abstain from alcohol start drinking because they believe it will lower their risk of heart disease," said Dr. Stephen Fortmann, associate director of the Stanford Center for Research in Disease Prevention (SCRDP). "There are too many potential psychological, social and physical risks associated with alcohol use, particularly for persons who do not customarily indulge in alcohol," said Fortmann.

The study, conducted under SCRDP auspices and reported in the Friday, May 17, issue of the **Journal of the American Medical Association**, was done as an extension of a summer project by Stanford human biology student, Carlos Camargo Jr., whose undergraduate research was sponsored by the American Heart Association. Camargo currently is a first-year medical student at the University of California San Francisco.

Other authors were Paul T. Williams and Karen M. Vranizan, SCRDP biostatisticians; John J. Albers, a blood fat researcher at the University of Washington School of Medicine; and Peter D. Wood, a blood fat researcher and associate director of SCRDP.

A study of 24 healthy men showed that alcohol clearly increased their average levels of a substance called apolipoprotein A-I, which has been shown in earlier studies to be strongly linked to reduced risk of heart disease. When some of the men stopped drinking, their level of Apo A-I decreased, said Williams.

Apo A-I is a component of the so-called "good cholesterol," high density lippoprotein (HDL). Persons with high HDL levels, including most athletes, are known to have a lower risk of heart attacks than persons with low levels. In recent years it was learned that APO-A1 is an essential, functional component of HDL.

Scientists believe that HDL lowers heart attack risk by clearing the arteries of fatty deposits. Another form of blood cholesterol, low density lippoproteins (LDL) have been shown to increase the risk of heart disease by causing fatty deposits in blood vessels.

Earlier studies have also shown that alcohol consumption increases HDL levels, but until this study was completed, it was not known whether the increase involved only inert components of HDL, which would rule out this blood component as a factor in reduced heart disease.

5-15-85

-more-

The SCRDP study also showed that moderate alcohol consumption increased the level of apolipoprotein A-II, but that protein's relationship to heart disease has not been clearly established, said Camargo.

The study was conducted on nonsmoking volunteers, aged 30 to 60, who regularly consumed two to three drinks per day.

After studying diet, alcohol consumption and exercise level for three weeks, half of the participants stopped drinking entirely, while the other half continued with their normal consumption. After six weeks, the abstaining group resumed normal drinking for five weeks of further study.

The diet and exercise level of all participants was monitored to eliminate these factors as an influence on Apo A-I levels. But Camargo said the study clearly showed that alcohol—in whatever form it was taken—was the dominant influence in changing the Apo A-I level.

Camargo said other studies have shown persons who drink moderately have a smaller risk for heart disease than persons who drink heavily or not all. However, he cautioned that it is impossible to determine precisely how much reduction can be achieved, since there are many factors involved in heart disease.

The amount of Apo A-I increase occurred in all of the drinking men studied, averaging about a 14 percent increase in persons who consumed about 2 1/2 drinks per day. But the amount of increase varied depending on a variety of physical and environmental factors, and there is no accurate way to determine how much risk reduction can be achieved from a given increase in Apo A-I level, Fortmann said. The Apo A-I level must be studied in a context of other important risk factors, such as smoking, exercise, blood pressure and general physical condition, he added.

Fortmann explained:

"This study provides some additional evidence that moderate drinkers—persons who limit their intake to about one drink a day—may derive some modest cardiac benefits, particularly if their diet, exercise and lifestyle patterns are otherwise healthy.

"As a general rule, I would not recommend that anyone start drinking to benefit their health. There are many other ways to help protect against heart attack—exercise, diet, weight control—that do not carry the risks of alcohol. But for adults whose habits include a stable, modest alcohol consumption, there may be some protection against heart attack and one need not recommend that they stop drinking," Fortmann added.

ALUMNI BROTHERS INITIATE VISITING MEDICAL PROFESSORSHIP

STANFORD—

Ben and Jess Shenson, brothers who both graduated from Stanford Medical School and have had a lifelong commitment to clinical medicine, have established a visiting professorship intended to bring an outstanding academic clinician to Stanford for one month.

The Dr. Ben and A. Jess Shenson Visiting Professor of Clinical Medicine in memory of Louis and Rose Shenson, the benefactors' parents, was announced this week by the university and the Shensons. The two brothers have practiced internal medicine at the same location in downtown San Francisco for more than 30 years.

Dr. Rex Jamison, acting chairman of the Department of Medicine, said the visiting professor will conduct clinical rounds, occasionally lead grand rounds, and meet with faculty, students and house staff.

"In sum, the purpose of these activities will be to reaffirm the art of the clinician amidst the increasingly impersonal and administrative aspects of modern medical care," Jamison said.

The first recipient selected by the Shensons on the recommendation of a faculty committee is expected to be at Stanford in early 1986. The visiting professorship has been established for one year with the intention of becoming longterm, the Shensons said.

Ben Shenson graduated from Stanford Medical School in 1940, while Jess followed with his M.D. in 1950. Both brothers also received their undergraduate training at Stanford.

The two physicians served on the clinical faculty until the medical school moved from San Francisco to Palo Alto. For many years, both continued an active clinical appointment on the faculty by commuting to Palo Alto to teach.

The Shensons have continuously been active financial supporters of Stanford. In 1950 they established a medical student loan fund, now known as the Louis and Rose Shenson Memorial Loan Fund. Rose Shenson shared her sons' interest in Stanford and often accompanied them to campus events until her death at age 90 in 1983.

The brothers have a strong interest in the arts, particularly the opera and have collected the work of early California artist Theodore Wores.

NEW CLINIC FOR PEOPLE WITH FACIAL PARALYSIS OPENS AT STANFORD

STANFORD—

A new multidisciplinary Stanford University clinic for patients suffering facial nerve damage offers hope to those who may have thought nothing could be done for paralysis.

"The face is very important," said ear, nose and throat specialist Dr. Richard Goode, coordinator of the clinic. "You can't cover it up with clothes. If it doesn't work it can affect a person's appearance, speech, eating ability and more."

Facial paralysis can be caused by viruses such as Bell's Palsy, tumors, strokes and other conditions, Goode explained. Patients of the clinic—the only one of its kind in this area, Goode said—will have access to physicians in a variety of specialties, such as neurologists, ophthalmologists, and surgeons, as well as physical therapists and psychologists. They will be provided with a consultation covering all aspects of their facial nerve disorders including diagnosis, treatment and longterm prognosis.

"I was in a state of dispair," recalled Los Angeles resident Barbara Horrall, who was told by numerous physicians she saw in Southern California that her partial facial paralysis was due to a tumor that would require "radical surgery. They said they would have to take out the tumor, disconnect nerves, do skin grafts, the whole works."

The paralysis to the right side of her face had come on gradually over a period of about three years, Horrall explained. By the time she finally noticed it, the muscle tone in the right side of her face had deteriorated considerably.

"My face was distorted," Horrall said. "I'm an English teacher and I've always enunciated very well when I talk. I had to learn not to move my mouth.

"I was asked to substitute for a teacher for six months and I refused. I was too embarrassed. I thought the kids would laugh at me."

Dissatisfied with the physicians and upset with his wife's vanishing sense of confidence, Horrall's husband called Stanford and was referred to Goode and neurologist Dr. David Prince. They ruled out the possibility of a tumor as well as surgery to remove it. What they did instead, Goode explained, was surgically alter some of the muscles on the left side of Horrall's face so that its function matched that of the right side.

"My face isn't perfect, but it's a lot better," Horrall said. "I'm not so self-conscious anymore."

Would she accept a teaching position today? "You bet," Horrall affirmed.

"There are so many cases like this where patients want a second opinion but have no where to go," Goode said. "Many physicians can provide the expertise in their own area, but do not consider the rest of the face.

"What this new clinic does is bring together all the available information and collective experience in one place," he said. "Our goal is to coordinate care for patients so they don't have to run from one physician's office to another."

SYMPOSIUM DISCUSSES STRATEGIES FOR GENE THERAPY

STANFORD—

Attempts to treat human disease using "gene therapy" techniques will begin earlier than three years from now and possibly within one year, predicted Dr. Paul Berg, professor of biochemistry at Stanford University School of Medicine.

Berg made his remarks at a press conference Thursday, May 9, held in connection with the third annual symposium of the medical school's program in molecular and genetic medicine.

The press conference marked the public announcement of plans for construction of a new $50 million building to house the molecular and genetic medicine program, headed by Berg, a Nobel laureate.

The first diseases to be treated through gene therapy most likely will be those caused by a defect in a single gene, Berg said. Dr. David Martin, vice president for research at Genentech, Inc. of South San Francisco, is one of the researchers contemplating such gene therapy clinical trials.

Martin, who has targeted two rare genetic diseases of the immune system for gene therapy, was one of the speakers at the scientific symposium which focused on causes, diagnosis, and treatment of genetic diseases—particularly those of the human immune system. The daylong symposium drew a full crowd of students, faculty, scientists and reporters to Sherman Fairchild Auditorium.

Martin has been studying two immune deficiency diseases, each of which is caused by a defect in a single gene. In each case, the gene defect causes an important enzyme required for normal functioning of immune system cells to be missing.

(The diseases—called adenosine deaminase deficiency (ADA) and purine nucleoside phosphorylase deficiency (PNP)—are named after the missing enzymes.)

In both diseases, patients can be treated if the missing enzyme is supplied. This has been done through transplantation of bone marrow cells or infusions of red blood cells, Martin said, but both of those treatment methods have drawbacks.

Martin outlined his proposal to use a genetically engineered virus as a ferry that could carry a normal "healthy" gene into patients to supply them with the enzyme their own defective gene cannot provide. Martin and his collaborators have already succeeded in transferring ADA and PNP genes into mice with this method, although they have yet to prove that the gene transfer results in production of the needed enzymes.

However, once that is accomplished human clinical trials might come soon. (The National Institutes of Health committee overseeing the introduction of gene therapy clinical trials recently recommended suspension of the requirement for experiments in primates prior to commencing gene therapy studies in humans.)

ADA and PNP are good candidate diseases for gene therapy, Martin stressed, since patients afflicted with them are "time bombs" who can die at any moment but if treated can live completely normal lives.

In addition, gene therapy for ADA and PNP does not present two of the formidable technical obstacles that would-be gene doctors will have to master for more complex diseases: making sure that genes are transferred only into specific tissues where they can provide benefit and making sure that they neither produce too much nor too little of the proteins they specify.

In ADA and PNP, Martin explained, therapeutic effects can be achieved even if the level of enzyme produced is not finely controlled and whether or not the new gene is placed or expressed only in certain specific cells.

Another method of transferring healthy genes into a patient to supplement or replace malfunctioning ones is bone marrow transplantation, which was discussed by Dr. Donnall Thomas from the University of Washington and the Fred Hutchinson Cancer Center in Seattle.

Thomas suggested that bone marrow transplants provide a more natural way of transferring therapeutic genes since the healthy genes are "packaged" in human bone marrow cells rather than in genetically engineered viruses.

Thomas reported on survival rates following bone marrow transplantation in patients with a variety of immune deficiency diseases and enzyme deficiences. But the requirements of finding matching donors, controlling rejection, and preventing donor cells from attacking recipients' tissues are still problematic, Thomas said.

Bone marrow transplantation can be considered a form of gene therapy, Thomas said, although in some cases, such as in cancers of the immune system, the underlying genetic defects causing the disease are not yet understood.

An alternative form of treatment for certain cancers of the immune system was reported on by Dr. Ronald Levy, associate professor of medicine at Stanford. Levy presented results from four years of clinical tests at Stanford with "tailormade" proteins known as monoclonal antibodies in 11 patients with cancers that affects cells in the immune system known as B-cells.

One patient's cancer receded within six weeks after he received doses of a monoclonal antibody tailor-designed to home in on his tumor, and the cancer has not reappeared in four years of follow-up, Levy said. Results in the ten remaining patients, most of whom had failed to improve with conventional anti-cancer therapy, were not as dramatic, although they are "encouraging," Levy said.

Five of the remaining 10 patients experienced at least a 50 percent shrinkage of their tumors, he reported, although in four the tumors returned within one to six months. In five other patients, the monoclonal antibody therapy showed no clinically significant effects, he said.

Levy said that further studies are needed to improve the clinical results and to determine how the monoclonal antibodies may achieve their anti-tumor effects. Some evidence suggests that monoclonal antibody therapy may work best in patients whose immune systems are already attempting to destroy their cancers.

Berg, who said that "all human disease is genetic in its origin," noted that defects in single genes account for 350 to 400 known human diseases. But many others are caused by the interactions of more than one defective gene.

"Schizophrenia and several forms of heart and hypertensive diseases" may fall in this category, he suggested.

Other examples of "polygenic" diseases are the so-called autoimmune diseases such as rheumatoid arthritis, juvenile diabetes, multiple sclerosis, and myasthenia gravis. Dr. Hugh McDevitt, Stanford professor of medical microbiology and medicine, discussed how genetic research is leading to new ways of diagnosing people who are highly susceptible to developing these diseases.

Certain genes associated with the immune system contain subtle variations from person to person, McDevitt explained. But individuals with multiple sclerosis all seem to possess one particular gene form while those who develop arthritis have in common a different gene variant.

-more-

By developing ways of detecting these gene variations, scientists open up the possibility of diagnosing susceptible individuals as early as prenatally. Then, if preventive techniques such as vaccination are found, the susceptible people could be protected from developing disease. And as new therapies for these diseases become available, susceptible individuals could be treated at the earliest stages of disease for maximum effectiveness, he said.

One such new treatment strategy McDevitt described is an attempt to use monoclonal antibodies against multiple sclerosis. Earlier this year, Dr. Lawrence Steinman of Stanford, with colleagues reported encouraging results in mice in both prevention and reversal of an experimental disease considered a model for multiple sclerosis. Clinical trials in humans could begin within the next year, Steinman has said.

Several morning speakers concentrated on advances in understanding the basic biology of the immune system. Dr. Irving Weissman, professor of pathology, described recent research on the receptors immune system cells use to get where they need to go in the body. These "homing" receptors may provide useful diagnostic information to predict where immune system cancers might spread through the body, he said.

Dr. Mark Davis, assistant professor of medical microbiology, discussed the genes that code for "recognition" receptor proteins of immune system cells. He described some of the parallels and differences between the receptor genes for T-cells—the immune system cells involved in tissue rejection and regulation of the immune response—and receptor genes in B-cells, which play a role in fighting viral and bacterial infections. These receptor proteins enable immune system cells to recognize foreign substances and tissues in the body.

Dr. Leroy Hood, professor of biology from California Institute of Technology in Pasadena, also described work on the genes that code for the immune system's receptor proteins. Automated instrumentation in his laboratory is helping scientists find the DNA sequences of newly discovered genes and construct proteins coded for by those genes.

COMPETITIVE TRENDS IMPORTANT IN PLANNING M.D. CAREERS, PANEL SAYS

STANFORD—

The practice of medicine is a business, and those preparing for it should take that into account when planning their careers, a panel of doctors agrees.

The physicians, all from diverse backgrounds, met at the Stanford University Medical Center on Tuesday, May 7, to discuss what medicine will be like in the year 2000. All felt that increased bureaucracy in medicine probably will affect the interpersonal relationship between doctors and patients in the future.

And the doctors stressed that the economic realities of practicing medicine and the stiff competition for patients were areas they hadn't adequately evaluated as students.

Dr. Rosaline Vasquez, a practicing physician at the Redwood Medical Clinic, says she went to medical school with the intention of serving the Spanish-speaking population. She said she and her husband, also a physician, opened an office in a small town.

"The first year we lost $40,000," Vasquez said. Established physicians in the area, apparently fearing the competition, did not readily welcome them, and there was a fight over restrictions of hospital privileges, said Vasquez. The cost of equipment and overhead was high. "Finally, we came back and joined a 40-doctor multi-specialty group in Redwood City," she said.

Dr. Roger Peeks, who is in private practice in Oakland and assistant dean (Minority Affairs) at the Stanford University Medical School, told the some 120 persons attending the discussion he felt more and more physicians would shift from private practice toward group practices or working for pre-paid health plans. Peeks said that undoubtedly would reduce the amount of time most doctors would spend with each patient.

Dr. Patricia McGann, practicing physician at the Mid- Penisula Health Clinic in Palo Alto, a consumer-owned health care service, said, "Very few professions have enjoyed the amount of autonomy physicians have in the past. I think it's unrealistic to think we'll be allowed to continue without restraints."

Dr. Thomas Fiene, a practicing internist at Menlo Medical Clinic, said he thinks doctors "have an awfully long way to go in how we relate to our patients. how we guard the professional relationships, how we act as their advocates."

He also sees "a trend of increased care of patients at home" because the cost of hospital care is so high.

All the doctors felt that students should look realistically at the economics of medicine in planning their careers.

-more-

5-13-85

Dr. John Harris, physician and administrator of the Fremont satellite facility of the Palo Alto Medical Clinic, went to business school after getting his medical training, and he found the knowledge he gained useful.

Dr. Ann Arvin, associate professor of pediatrics at Stanford University Medical School, said, "I'm a little uncomfortable that we're spending so much time talking about money...The reason we keep talking about money is that it is a real factor in our lives and I don't know any profession where that wouldn't be true."

All the doctors agreed that the future will see medicine belonging more to large health-care corporations and prepaid health plans, which will employ doctors on salary, rather than to the private practitioner.

And that, the physicians said, will mean spending less time with each patient.

In the future, Vasquez said, "things like developing a personal relationship will be left as a last priority."

Eventually, she feels, patients' expectations of their doctors also will change. "Patients will no longer expect their physicians to be available at all hours, 365 days a year," Vasquez said.

McGann felt some of the major changes in the future will come from "increased consumer involvement in decision-making. Patients have a strong desire to be educated about...what's going to happen to their bodies and their lives," she said.

New technologies will make a difference in treatment, the physicians agreed. "I think probably the quality of care will be better because of technology," said Peeks, "but you may not be better off in terms of a personal relationship with your patient."

Vasquez said, "I think there will be a crossing point at which the patients will say, 'Hey, wait a minute. I want more personal care, and I'm willing to pay more for it.'"

The group discussion was moderated by Dr. John Bunker, professor of anesthesia and health policy researcher.

FOR IMMEDIATE RELEASE

NEW DIVISION OF HAND SURGERY ESTABLISHED

STANFORD—

Stanford University School of Medicine has established a new division of hand surgery, announced Dean David Korn.

The division—the first ever at a major medical school—grabs onto a national trend leading towards the creation of hand surgery as a new medical specialty, said Dr. Vincent Hentz, head of the new division.

The advent of microsurgery—techniques with which surgeons can cut and splice vessels, nerves, muscle, tendons and more with minuscule tools they maneuver while peering through a microscope—enhanced the young specialty. The techniques gave physicians the ability "to cope with any of the deformities that occur within a hand whether they result from injury, birth defect, lost of part due to infection or treatment of tumors or degenerative disease," said surgeon Dr. Robert Chase, who will join Hentz as a faculty member for the division.

"Within two years there will be some type of national certificate of special competency in hand surgery," Hentz predicted. Other schools will be scrambling to develop a curriculum to satisfy the requirements for the specialty while Stanford's division will be up and running, he added.

"Stanford is wise to establish this division now," he said.

The hand is of interest to surgeons, Hentz explained, because of its relative importance—it is one of two elements that separates man from other animals. The other is man's highly developed brain.

The goals of the new division are to provide academic and clinical training to medical students, postdoctoral students, interns and residents, Hentz said, as well as to develop a "first class patient care facility." In addition to Hentz, a plastic and reconstructive surgeon who has for the last 10 years specialized in hand and microvascular surgery, and Chase, internationally known as one of the "deans" of hand surgery, Dr. Vincent Pelligrini, an orthopedic surgeon currently at Unviersity of Rochester, New York, will join the faculty this summer.

"The combination of expertise among the faculty is unique," Hentz said.

Surgery of the hand and upper extremities began its evolution as a specialty during WWII, Hentz explained. General; plastic and reconstructive and orthopedic surgeons became intrigued with the specialty because of the hand's function and opportunity it provides for research and discovery. Two national organizations with about 2,000 members now exist for physicians specializing in this area.

ADVANCE FOR RELEASE AFTER 2:30 P.M. THURSDAY, MAY 9, 1985

BECKMAN FOUNDATION GIVES $12 MILLION TO STANFORD FOR NEW MOLECULAR AND GENETIC MEDICINE CENTER; COMMITMENTS TO DATE BRING CENTER CLOSER TO REALITY, SAYS STANFORD PRESIDENT

STANFORD—

The Arnold and Mabel Beckman Foundation has announced a $12 million gift to the Stanford University School of Medicine towards construction of a new $50 million Center for Molecular and Genetic Medicine which will allow scientists to bridge molecular biology and clinical practice—a field that promises dramatic changes for medicine in the future.

The announcement of the gift was made by California philanthropist Arnold O. Beckman, founder and chairman of Beckman Instruments, and Stanford University President Donald Kennedy at a press conference held Thursday, May 9, at Stanford University in conjunction with the Third Annual Symposium of the Program in Molecular and Genetic Medicine.

A commitment, Kennedy said, has also been made by the Howard Hughes Medical Institute for $17 million in advanced lease payments to aid in the construction of space in the building to house a Hughes laboratory unit in molecular and genetic medicine. Dr. Donald Fredrickson, president of the institute, also participated in the press conference.

The occasion marked the first public announcement of the university's plans to proceed with the establishment of a new academic program designed to apply basic knowledge from molecular biology to vexing problems of human disease and to construct a new center for the multidisciplinary research effort under the direction of Nobel Prize winning biochemist Paul Berg.

The new center will contain four programs, including Stanford's renowned biochemistry department which is in need of new facilities, Kennedy said. The gift will build the Arnold and Mabel Beckman Laboratories of Biochemistry in the Center for Molecular and Genetic Medicine.

"This generous gift," Kennedy said, "brings us a step closer towards the realization of our fundraising goal for the center. It comes also at a critical time in which the future underpinnings of health research depend on capital for new laboratories and equipment—something the federal government has neglected to provide for the past 15 years."

"A large part of the impetus of the genetic revolution grew out of research in biochemistry at Stanford under the leadership of Drs. Arthur Kornberg and Paul Berg," Dr. Beckman said. "My purpose is to help guarantee that biochemistry at Stanford will remain strong and be able to contribute to the next revolution of biomedical advances."

The Beckman Foundation, based at Corona Del Mar in Southern California, was established by Dr. Beckman, a leading scientist, whose firm has pioneered in the development of precision instruments and related products for medicine, science, industry, environmental technology and other fields.

Dr. and Mrs. Beckman have been donating substantial sums to the advancement of education and research for many years. The beneficiaries have included the California Institute of Technology, the University of Illinois, Rockefeller University, the Beckman Research Center at City of Hope in Duarte, and the Beckman Laser Institute and Medical Clinic of the University of California at Irvine.

-more-

"The concept of the Center for Molecular and Genetic Medicine represents not only a new and interesting approach to science, but an institutional experiment on how to make the process of innovation work better," said Kennedy in remarks prepared for the press conference. "Anybody who has looked at the history of biomedical research and its relationship to applications in clinical medicine is struck by how slowly even the most important basic advances are translated into procedures, devices, drugs or ways of intervening in order to improve the human condition."

Stanford is widely recognized for its pioneering work on the development of the new biology and the molecular cloning method which has allowed scientists to study genes and their role in disease. "We have the tradition and the experience," Kennedy said. "The determination is there, and now we are close to having the resources."

The new center has been in the planning stage for about two years. In addition to the Beckman Foundation gift and Hughes Medical Institute commitment, its construction will be sought from several other sources, Kennedy said.

The Institute-leased space will house about 10 Howard Hughes investigators who will hold full Stanford faculty appointments. Under a separate commitment, Hughes will also fund those scientists' research. Altogether the new center will involve about 40 scientists in several interrelated academic units—the Hughes laboratory unit in molecular and genetic medicine, a new department of molecular and developmental biology, a department of molecular and cell physiology, and the department of biochemistry whose laboratories will bear the Beckman name.

Staffed by eminent scientists and clinicians when it opens in 1988, the center will maintain a unified program devoted to a molecular understanding of critical biological functions, how these are affected by disease, and the potential applications of the new biology ranging from advanced therapies for cancer and diseases of the immune system to correction of genetic defects.

Complementary to the new programs will be a parallel expansion of medical school efforts in such areas as bone marrow transplantation, clinical genetics, gynecology and obstetrics, pathology, and pediatrics, all of which will play a major role in molecular approaches to treatment and gene therapy.

Berg described the center as one of the most ambitious projects ever undertaken at Stanford. "It's natural that it should happen here," he said. "In addition to its science strengths, the character of the medical school permits a contiguity of medical expression with clinical science." The other ingredients listed by Berg include:

- a comprehensive academic medical center comprising a university-owned hospital, outpatient clinics, and a school of medicine under one roof
- a faculty with a demonstrated capacity to transfer basic discoveries from the laboratory to the bedside in such areas as cancer therapy, immunology, and organ transplantation.
- an environment that attracts some of the best faculty, students, and postdoctoral fellows, and
- proximity of the center to a major research university with renowned programs in biology, chemistry, clinical medicine, computer technology, engineering and physics.

Dr. Beckman is a native of Cullom, IL. He holds a master's degree in physical chemistry from the University of Illinois, and a doctorate in photochemistry from the California Institute of Technology where he served on the chemistry faculty. In 1940 he left Caltech to devote full time to the development and manufacture of scientific instruments. In 1982, Beckman Instruments merged with SmithKline Corporation, one of the world's leading health care and life sciences companies.

NURSES CAN THRIVE IN HEALTH CARE CHAOS, NURSING LEADER SAYS

STANFORD—

Nurses are the only members of the health care team whose priority remains patient care, claimed one of the nation's nursing leaders.

"Physicians increasingly have taken on the role of technologists and hospital administrators have taken on the role of businessmen, while nurses are the only members of the health care team to whom patients are still the primary concern," said Dr. Pamela Maraldo, executive director of the National League for Nursing (NLN) at a breakfast speech May 8 at Stanford University Hospital.

This role change is part of a revolution in health care, she explained, caused by a new federal- and state-imposed health care system of scarce financial support, limited third party payments, diagnostic related groups and other payment schemes—all of which are intended to limit payment for health care services.

However, in the midst of this health care revolution the cutbacks have created, Maraldo continued, the nursing profession can thrive.

"In the midst of the doom and gloom of stringent state and federal budget cutbacks, and with the promise of more to come, nurses can find tremendous opportunity," she said.

But to take advantage of the current opportunities to be involved in shaping health and social policy, she stressed, "nurses must acquire financial independence.

"We must have control of the health care dollar—at least our share of it—in and out of hospitals," Maraldo said.

Nurses need to stress the profession as a viable alternative to providing many services including those included in primary health care that physicians now almost exclusively provide, she said.

Nurses can pick up the slack in providing quality care for reduced cost in a number of ways, Maraldo explained, such as:

* *Keep patients out of the hospital.* In hospitals, Maraldo said, good nursing care can decrease the length of patient stays "without question," while out of hospitals community nurses can provide primary care services, thereby eliminating the need for hospitalization.

- *Shift from acute care to community care*. Nurses should expand their role of providing services and consultation to clients in homes, schools, industries and clinics. These could include, Maraldo said, adult day care centers, home health care agencies, nursing homes and hospices.
- *Respond to changing demographics*. The elderly population is expected to increase as much as 100 percent by the end of the decade, Maraldo said. This creates a need for care of chronic illnesses, which constitute the majority of the elderly's health problems. "The treatment of choice for chronic illness, of course, is nursing care," she said.

Consumers are dissatisfied with hospitals, medical care and health care costs, Maraldo said. "Nursing can emerge as the linking pin between cost and quality."

This health care revolution stems from severe budget cutbacks instituted by the federal government in an attempt to put a cap on spiraling health care costs.

"Every character in the health care play was seriously affected," Maraldo said. "Hospital occupancy rates dropped dramatically because people could no longer afford to pay for hospitalization at a time when hospitals could no longer afford people who could not pay."

Policy makers are looking to prevention as "the great white hope" for decreasing health care costs and improving the quality of people's lives, Maraldo continued. Nursing is already focused on prevention, she said. "Preventing disease and promoting health is what nursing science is all about."

Maraldo presented the keynote address hilighting Stanford Nurse Week. Activities for the week also included a hospital-wide health fair May 4 at Stanford Shopping Center, and a 10K fun run scheduled for May 12.

Maraldo has been with the NLN since 1977, and has held the position of executive director since 1983. She is noted for establishing a more active role in government health care policy for the NLN, a coalition of nursing leaders, educational programs, institutional and community health nursing services and consumers working towards the betterment of nursing. Maraldo received a Ph.D. in nursing at New York University in 1984.

MALPRACTICE, SCIENTIFIC TOPICS TO BE DISCUSSED AT STANFORD MEDICAL ALUMNI REUNION

STANFORD—

Dr. David Rubsamen of Berkeley, an authority on medical malpractice, is scheduled to be the keynote speaker at the spring alumni reunion of the Stanford Medical Alumni Association May 18.

Rubsamen, editor of the *Professional Liability Newsletter*, plans to discuss "Prospects of Dramatic Changes in the California Malpractice Scene." His address to more than 50 alumni, spouses and guests scheduled to attend the all-day event follows a morning scientific session in Stanford medical school's Sherman Fairchild Auditorium.

An alumnus of Stanford medical school and Stanford law school, Rubsamen provides consultation on medical aspects of litigation for attorneys who represent physicians. The newsletter, which he has edited since 1968, outlines and comments on current legal-medical decisions and how they affect California physicians.

The morning program includes sessions by faculty members from the departments of medicine, psychiatry and behavioral medicine, surgery and pediatrics. Topics include a Hodgkins disease update, care of the dying and bereaved, growth and growth hormones and low back pain.

Class reunions are scheduled for graduates of the classes of 1935, 1960, 1940,1950, 1955A, 1955B, 1965 and 1970 during the evening.

For more information call the Stanford University Alumni Association at 415-497-6389.

FEDERAL FUNDING CUTBACKS THREATEN CURE FOR THIRD WORLD SCOURGE

STANFORD—

Paul F. Basch had false confidence that he could escape federal budget cuts for his research into a disease which afflicts 200 million persons worldwide.

The panel of scientists responsible for reviewing the Stanford University Medical Center scientist's funding had recommended "approval with considerable enthusiasm," noting that Basch's studies of the third world scourge called schistosomiasis had in recent years "led to several very important and exciting discoveries."

But in February, funding ranging from $142,134 to $158,229 for each of the fourth, fifth and sixth years of his project was abruptly put on hold, and most of his laboratory staff—including a research associate, a lab technician and a glassware washer—had to be laid off.

The project was studying the reproductive biology of schistosomes, the worms which enter the body, and then deposit eggs in the blood stream, causing liver and other internal damage.

Basch, a parasitologist and professor of Family, Community and Preventive Medicine, said he hoped to understand the lifecycle well enough to find a way to interrupt it, and thus save millions of residents of third world countries from the debilitating chronic infestation. The World Health Organization said the disease is present in 74 developing nations in the tropics and is spread by contact with fresh water.

Basch and the dean's representative responsible for reviewing research funding at Stanford Medical School—Elwood Pierce—point out that it is unusual for a highly rated project praised by reviewers to fail to receive renewal funding. Moreover, both Basch and Pierce said they were convinced that the project would have been continued were it not for the Reagan administration decision in January to reduce the number of funded National Institutes of Health projects by 23 percent.

Projects are rated on a point system by a panel of scientists with expertise in the field. The rating is confidential, but both Basch and Pierce, the medical center's operation director, said the score assigned by the panel which reviewed Basch's application—The Tropical Medicine and Parasitology Study Section—would have been high enough to assure funding prior to the admnistration cuts. The administration reduced from 6,500 to 5,000 the number of projects to be funded.

The Department of Health and Human Services, which oversees funding of the National Institutes of Health grants, told Basch in a Feb. 5 letter that the agency would hold the application for the project until the fiscal year ends Sept. 30, pending availability of new funds.

5-7-85

-more-

"But that's not really practical. I've already had to shut down most of my project. We're dealing with a live organism which must be maintained continuously," Basch said. He said the material needed to study the lifecycle had been carefully cultivated "and if we had to stop completely it would take us many months to build our material back up.

Basch said he has been able to keep his lifecycle study at a minimal level only with the help of his wife, a trained laboratory technician.

Tag E. Mansour, chairman of the Department of Pharmacology and an authority on parasites, said Basch will continue to share some research funds from a $1.5 million, five-year grant funded by the John D. and Catherine T. MacArthur Foundation of Chicago.

But loss of the federal grant and shutdown of the project will at least involve a delay in finding a solution to schistosomiasis.

Mansour said a decision to halt research on that parasite is shortsighted, because the condition, while rarely fatal, causes chronic ill health and loss of productivity in its victims.

Current treatment require many months of expensive and potentially toxic drugs, Mansour said.

Mansour said:

"One of the major obstacles to progress in the Third World is the inability of people to be productive at work because of chronic diseases such as schistosomiasis. We can spend billions of dollars in foreign aid, but if the population we are trying to help to become productive is chronically ill, all other forms of assistance will be wasted."

While limited to the tropics and largely eliminated from developed nations even in warmer climates, schistosomiasis is a threat to Americans and other visitors to the third world countries who must avoid even washing or bathing in many otherwise safe sources of fresh water.

STANFORD BLOOD CENTER USES NEW AIDS SCREENING TEST

STANFORD—

The Stanford University Blood Center has substituted the test procedure it pioneered for AIDS with a new highly-publicized screening test, officials announced last week.

"Fortunately, to date, no patient who has received T cell tested blood from our blood bank has contracted AIDS," said Dr. Edgar Engleman, associate professor of pathology and medicine and medical director of the blood center.

"Nonetheless, the new HTLV-III (AIDS virus) antibody test appears to be more specific and at least as sensitive as the T cell test and, therefore, as of April 1985, the T cell screen has been replaced with the AIDS virus antibody test."

Engleman said the decision "is consistent with the Stanford University Blood Bank policy of making every effort to ensure a safe blood supply."

Stanford became the first blood bank in the nation to begin screening blood for the deadly AIDS on July 1, 1983, Engleman said.

Engleman said the HTLV-III is more specific than the test Stanford has been using because it screens for evidence that the donor actually has been exposed to AIDS, rather than for the highly-accurate but indirect evidence of measuring T-cell ratios.

The HTLV-III measures the presence of antibodies to what is believed to be the AIDS virus. The Stanford test detected an abnormal ratio in the white blood cell composition which is common to AIDS sufferers.

A drawback to the Stanford test was that the abnormal ratio of "suppressor T-cells" to "helper T-cells" detected in the screening was also present in some persons who do not have AIDS, said Engleman. That meant healthy blood from about 1.5 per cent of Stanford's donors had to be eliminated because those test results were positive, he added.

In the past several months, many blood banks in the Bay Area and elsewhere have begun using the HTLV-III test routinely.

Abbott Laboratories Inc. of North Chicago, Ill., makes the serum for the HTLV-III screening.

In a related matter, Rhoda Burns, Stanford's blood donor coordinator, said donations have dropped about 7 per cent in the last few months, primarily because of student donor schedules. Stanford's goal, she said, is to average 1,550 units per month.

"We depend so heavily on Stanford students for blood donations," said Burns. "The students are taking finals this month and then, they'll be leaving for the summer. Our need for donors is very great now, especially because a lot of people schedule elective surgery during the summer because it's a good time for them to take time off work."

JOURNALIST/PHYSICIAN LAWRENCE ALTMAN TALKS AT STANFORD

STANFORD—

New York Times medical reporter Dr. Lawrence Altman will be the featured speaker at Stanford Medical Center Health Services Research Seminar from 4 to 5:30 p.m., Monday, May 13 at Schultz Auditorium.

Altman, a practicing internist as well as a journalist, will discuss, "Responsibility of the Scientist and the Media to the Public."

Altman is expected to discuss ethical and medical issues based on his own experience on such stories as implantation of permanent artificial hearts in Salt Lake City and later Louisville.

He has been a critic and observer of both the ethical and public information issues involved in the Baby Fae case, the implantation of a baboon heart in a newborn girl at Loma Linda University last year.

MEDICAL SCHOLARSHIP HONORS STANFORD'S FIFTH PRESIDENT

STANFORD—

A Southern California insurance executive with a long history of support for Stanford has pledged $250,000 to create a medical scholarship fund in honor of J.E. Wallace Sterling, the university's fifth president.

The J.E. Wallace Sterling Medical Scholarship Fund creates an endowment that will support the work of a number of medical students by returning more income than the typical scholarship fund, said Sally Agle, associate director of medical development.

Scholarship donor John C. Cosgrove and Sterling's paths crossed significantly 25 years ago, when the supporter and his wife, Emilie Dohrmann Cosgrove, became major donors in the 1959 relocation of the School of Medicine from San Francisco to the Palo Alto main campus.

Sterling, currently chancellor, was university president then and "the driving force in the relocation," said current Stanford President Donald Kennedy.

Cosgrove's gift is particularly aptly named, Kennedy said, because Sterling has contributed "in such a special way to the remarkable advances that Stanford has made among the great universities of this land."

Medical School Dean David Korn called the fund "very fitting. Wally Sterling has a very special place in our affection here because of his role in creating the 'new' (Palo Alto) Stanford School of Medicine."

Cosgrove's formal relationship with Stanford began when he became an undergraduate in the class of 1934. In the early 1950s he was asked to join Stanford Associates, a selective volunteer fund-raising and advocacy group. Cosgrove accepted, noting his "very high regard for President Sterling."

From 1964 to 1967, Emilie Cosgrove was one of the first women trustees of the university.

For several decades, Cosgrove has financially supported numerous educational and medical programs, including the Willard W. Keith Jr. fountain near Memorial Church, the Frederick W. Dohrmann Jr. classrooms at the medical school, as well as programs in respiratory medicine, psychiatry and a variety of other departments at the medical center and university.

DIABETIC VOLUNTEERS NEEDED FOR STUDY

STANFORD—

Diabetics currently being treated with oral medications or diet are still needed as volunteers in a Stanford study evaluating a new oral drug for diabetes.

Dr. Patricia Kapsner said participants must be in good health and between 40 and 70 years old. Volunteers will receive physical exams, blood work and electrocardiograms during the study. There will be an initial hospitalization of seven to 10 days, followed by five weeks of outpatient evaluation. All services are free and patients may be compensated for their time.

The study is being conducted under the direction of Dr. Fredric Kraemer, assistant professor of medicine. Kapsner said six volunteers were recruited in February and about six more are currently needed. For further information, contact Kapsner at (415) 497-6892 between 9 a.m. and 4 p.m., weekdays.

EDITORS: The press is invited to a first anniversary celebration of "Life Flight" at the Stanford University helipad on Friday, May 10 from 7 a.m. to 4 p.m. Photo available on request.

FOR IMMEDIATE RELEASE

LIFE FLIGHT CELEBRATES ONE YEAR

STANFORD—

As "Life Flight" completes its first year of service, medical personnel in the program agree that a number of lives were saved because of the emergency helicopter transport system.

"Life Flight," sponsored jointly by Stanford University Hospital and Santa Clara Valley Medical Center, has gone on almost 300 rescues since it began operation last May 1. The first month, there were 15 emergency calls. In April, "Life Flight" answered more than 50.

Flight Nurse Tony Leiker remembers one particularly dramatic rescue. A young motorcyclist went over the side of an embankment and his bike crushed his chest, puncturing both lungs, lacerating his heart and causing numerous fractures.

"This man surely would have died if he'd been transported by ground ambulance because he was bleeding so badly," Leiker said. "We got him to the hospital fast. He had surgery, and a few weeks later, he walked out. It's moments like that that make all of us feel pretty good."

The "Life Flight" medical team is airborne within three to five minutes of a request for assistance, officials say.

Dr. Myron Gomez, a flight physician, says it's impossible to know exactly how many lives might have been saved because 'Life Flight" was there, but clearly there were cases when the savings in time made the difference between life and death.

"There were incidents where we got in, picked up someone, and got back to the hospital in less time than it would have taken a ground ambulance to even get to the scene," Gomez said. "There were other times when we got to accident or heart attack victims in remote areas or where all the ground access routes were jammed by traffic."

Chief Flight Nurse Marcia Katz stressed that "Life Flight," which serves a 150-mile radius from San Jose, is more than a transport system. "It's an extension of the hospital emergency department," said Katz.

The helicopter is always staffed by an emergency-care physician and a nurse. "Life Flight" is the only helicopter service in Northern California that routinely flies with a physician on board.

"That means a lot in an emergency situation," said Dr. Dan O'Brien, "Life Flight" medical director. "If there's a doctor on the scene, he doesn't have to take the time to radio back to an emergency department, give a complete assessment of the situation and wait for medical instructions. He can take action at once. For example, a doctor can intubate a trauma victim, a skill that many paramedics aren't certified to do that."

" 'Life Flight' isn't trying to replace ground ambulance or paramedic services," said Katz, "but in certain instances, critically-injured victims can get care more quickly than they would otherwise and that can make a great difference."

Dr. Michael Eliastam, local "Life Flight" program director and chief of emergency services at Stanford, said, " 'Life Flight' represents a major cooperative venture between Stanford University Hospital and Valley Medical Center. What's been exciting is introducing the new technique into the Bay Area communities."

Shortly after "Life Flight" began, another helicopter ambulance service, Calstar, started in Northern California. Before those two airborne ambulances, the Bay Area received only limited emergency helicopter service from the California Highway Patrol, the Army at Fort Ord and the Coast Guard. Other than "Life Flight," the closest service that always flies with a physician on board is out of UCLA in Southern California.

The Twin Star "Life Flight" helicopter has enough cabin space for two patients, and it's equipped with intravenous equipment, medications, monitoring systems, extrication devices to stabilize a patient as he or she is being removed from a vehicle, built-in suction to clear airways, oxygen, compressed air and ventilator for respiratory assistance.

"It's amazing how often emergency calls come at exactly the same time," said Eliastam. "When that happens, we'll refer to Calstar. One goal is for 'Life Flight' to become part of a regional EMS (emergency medical service) network, where there are primary zones of responsiblity. My prediction is that in the future, more and more patients will be transported by air rather than ground."

ADVISORY ON SYMPOSIUM AND PRESS CONFERENCE TO BE HELD IN CONJUNCTION WITH STANFORD'S NEW PROGRAM IN GENETIC MEDICINE

STANFORD—

Science writers and city desks: On May 9, 1985 the Stanford University School of Medicine will host a day-long symposium on the "new genetics" both as a research tool and as it is expected to be applied to the study and treatment of disease.

The focus for the advancement of the applications of molecular biology to human disease will be a new $50 million Center for Molecular Biology and Genetic Medicine (CMGM) currently being planned at Stanford University Medical Center under the direction of Dr. Paul Berg, a winner of the 1980 Nobel Prize in chemistry, and scheduled for completion in 1988.

The new Center, which Stanford University President Donald Kennedy has described as "an experiment on how to make the process of innovation work better," will attempt to bridge the gap between the laboratory and medical practice by taking advantage of the powerful new tools of molecular biology.

Some key topics that will be be discussed at the symposium include "Strategies for Gene Replacement Therapy," "Immunodeficiency Diseases as Candidates for Gene Therapy," and "Bone Marrow Transplantation" presently regarded by scientists as the target vehicle for somatic cell therapy for certain genetic diseases.

The symposium will begin at 8:30 a.m. in the medical school's Sherman Fairchild Auditorium. A press conference is being planned for your convenience. Drs. Kennedy, Berg and guests will discuss the new center. The press conference will be at 12 noon in the Neurobiology Library of the Sherman Fairchild Building adjacent to the auditorium.

Copies of the scientific program are available if not included with this advisory. If you plan to attend, we urge you to fill out the coupon below and return it to the Stanford Medical Center's Office of Communications, 750 Welch Road, Suite #301, Palo Alto, California 94304. You may also let us know that you are coming or that you want a copy of the program sent to you by calling 415: 497-6911.

Send me a copy of the program.

STANFORD SCIENTIST REPUDIATES FALSE REPORTS ABOUT "SEXUAL STIMULANT" DRUG

STANFORD—

A Stanford University Medical School professor said today several publications are circulating false reports about his research on rats in which he is portrayed as endorsing a sexual stimulant for men.

"The reports say that I endorse the drug, yohimbine, as a sexual stimulant for humans. This is simply not true," said Dr. Julian Davidson, professor of physiology. "The implication that I and Stanford University have developed or endorse the use of these drugs is totally false.

"There is no adequate scientific evidence that the drug has any effect on human males' sex life," Davidson said.

A report in *Male Sexuality Report, Official Publication of Stamford (CQ) Center for Male Research* quoted Davidson and fictional patients about the effects of yohimbine, known in folk medicine as an aphrodisiac, as a product that stimulates and enhances men's sexual desire and performance. (While closely mimicking the University's name, the four-page advertisment has no address, phone number, or other identifiable orgin.)

A similar report in the tabloid *The Star* has been retracted at Stanford's request, said Susan deJongh-Kearl, Stanford University associate staff counsel.

"I never said anything they've quoted me as saying," Davidson said, "and the patients they quote do not exist."

Advertisers promoting yohimbine as a drug for human use have used Stanford University's and Davidson's name and work in an "improper and unauthorized" manner, deJongh-Kearl said.

"The University is concerned that consumers will be confused by this literature and incorrectly believe that Stanford University has developed or endorses the use of these drugs," she added. "The University is taking appropriate steps to halt this commercial use of its name."

Davidson has received many letters of complaint from people who have received the publications.

"There is no connection between these mail-order drugs and Davidson's research," deJongh-Kearl said.

Davidson, whose research focuses on the biology of human sexual behavior, published a report in the August 24, 1984 issue of *Science* magazine discussing his studies of the effects of yohimbine in male rats. The drug was found to strongly increase sexual drive in male rats, the *Science* article reported.

While Davidson is, in fact, conducting studies involving men, "it is way too early to reach any conclusions," he said.

Yohimbine, originally obtained from the bark of the tropical tree *Corynanthe yohimbe*, is now a synthetically manufactured prescription drug. It has also been used for depression and as an analgesic, Davidson said.

It is thought to increase the activity of norepinephrine, a natural chemical that certain nerve cells use to communicate with each other in the brain, Davidson explained. Norepinephrine and related chemicals called monoamine neurotransmitters may be involved with controlling sex drive, he suggested.

However, the drug's physiological effects in people may be different from those seen in rats, Davidson said. In addition, he added, human sexual behavior is complicated by the influence of emotional, social and other factors.

EMPLOYEE OF THE YEAR

STANFORD—

Stanford University Hospital's employee of the year thinks she "stood out" for recognition because she was seven months pregnant when she finished the testing of the hospital's new Admission, Transfer and Discharge (ATD) system.

Susan Taylor, assistant director for administrative services in patient admitting, says her co-workers joked that the baby's first words would be, "The system is down," or "This does not compute."

Taylor, who began working at the hospital in 1973 as an account representative in the billing office, received the Thomas A. Gonda Employee of the Year Award at a banquet Tuesday night, April 30.

In addition to the Gonda Award for dedicated and exemplary service, special awards were presented to five surprised "outstanding employees." They are: Karen Axnick, director of care review/risk management; Gloria Baskett, paratechnical supervisor; Judy Lanigan, assistant director nursing services; Annie Ketchens, cafeteria cashier; and Regina Lopez, pediatric nursing assistant.

The Employee of the Year, who described herself as "low key," stressed that implementation of the ATD system last Aug. 29 "was totally a team effort."

"We were all putting in incredible hours," said Taylor, "10 to 12 hours a day, six days a week. There was an enormous amount of data to enter into the ATD system and verify. And we were training the staff to use the new system."

Taylor says her husband, attorney Richard Dwiggins, was "extremely supportive" but her daughter, Alison, who was then a year and a half, "didn't understand why mommy was away so much. At one point, when my husband took her to the park, she went over to a strange family and asked if she could join their picnic because she saw a complete family together."

Taylor says she's proud to have been part of the team that implemented the new ATD system. "We had a manual system before, and the ATD probably cut the time it takes to do the paperwork in half."

Taylor, who worked two years to assist in developing the system, says that the savings in time allows the admitting staff "to help patients by answering questions rather than spending an enormous time on paperwork. All of us in this department are really committed to service, and the ATD assists us with that aim."

Her son, Rob, was born last Nov. 9, "just minutes after I arrived at the hospital, and my co-workers tease me that it now takes just minutes for the ATD to process the paperwork for newborns." Coincidentially, her daughter, Alison Taylor Dwiggins, has the same initials as the ATD.

The Thomas A. Gonda Employee of the Year Award, established in 1976, is named for the former hospital director who now serves as professor and chairman of the department of psychiatry and behavioral sciences. Gonda received his 30 year pin at the 27th annual employee service awards banquet Tuesday night.

Before the award bearing his name was presented, Gonda said: "I come to you as one of over 10,000 patients at Stanford each year...Some eight weeks ago, I underwent pretty major surgery. I got out in six days."

Donald Kennedy, president of Stanford University and chairman of Stanford University Hospital board of directors, said Stanford employees have proven that "compassion and caring can co-exist with academic excellence."

Daniel Robinson, director of personnel management and master of ceremonies for the event, noted that 540 employees and guests, representing 3,650 years of service, attended the dinner at Hyatt Rickeys. Pins and accessories for five, 10, 15, 20, 25 and 30 years of service were presented. Jean Laing, nursing, was named for 35 years of service, and Marguerite Brickner, nursing, was honored for 40 years of service.

LIFE FLIGHT PLACES SECOND HELICOPTER AT LAKEPORT THIS SUMMER

Eds: Pictures available if not included

STANFORD—

A second Life Flight emergency helicopter, sponsored by Stanford University Hospital (SUH) and Santa Clara Valley Medical Center (SCVMC), is scheduled to be launched Sunday, June 30, to serve Lake, Mendocino and surrounding counties for two months this summer.

Life Flight II is a cooperative venture with the health and emergency community in the largely rural area. The service will be headquartered at Lakeside Community Hospital in Lakeport.

The project was conceived about 4,500 feet above Clearlake in May, when a Lake County physician and a Stanford physician were caring for a patient.

Dr. Myron Gomez, a Stanford trauma fellow, and Dr. Richard Kurz, chief of staff at Lakeport's Lakeside Hospital and a family physician in Kelseyville, were transporting a 14-year-old girl to needed abdominal surgery at Sebastopol, a 20-minute helicopter trip.

As they provided care in the fully equipped airborne emergency room, the two physicians talked about how to reduce the one hour or more delay to secure a physician/nurse supported emergency medical air transport to the approximately 500,000 residents and visitors scattered over a 10,000-square-mile area of largely rural Lake, Mendocino and surrounding counties.

Specialized medical care is scattered in the forests, agricultural hillsides and rugged coastal areas of the lake region, North Coast and Wine Country, "and we had thought for a longtime that some sort of air service would provide a lifesaving benefit to end our medical isolation," said Dr. Dee Filgas, emergency department director of Lakeside Community Hospital, one of the organizers of the new service.

The airborne discussion in May led to a month of planning which is to culminate in the second helicopter at Lakeport during the busy summer months, when the population during some weekends can quadruple, said Dr. Michael Eliastam, director of the program.

Gomez estimated that the helicopter would provide one or two missions per day, about the same number as the Stanford-SCVMC-based helicopter. Nine nurses, with an average of 10 years trauma experience each, will rotate between the Lake County and Stanford/SCVMC bases.

Both helicopters are twin-engine French-built Aerospatiale Twin Stars leased from Rocky Mountain Helicopter Inc. of Provo, Utah. The aircraft, which can carry two fully-supported patients, cruise at 150 miles an hour with a top speed of 180.

Lakeside Community Hospital will supply a base, including on-call housing for the crew, said Eliastam, who is director of emergency services at Stanford.

Filgas said the service on the shores of California's largest lake is especially crucial in the summer, when tens of thousands of vacationers swell the local population, and boating and traffic accidents increase the need for emergency response.

-more-

Although Life Flight has responded to many calls in Lake and Mendocino counties since its inception in May 1984, the second helicopter will reduce the response time to the area by about 45 minutes, said Eliastam. "That time can be crucial both for patient safety, and particularly for accident patients, airborne response available immediately can mean a substantial reduction in suffering," he said.

Eliastam and Filgas both said they envision that the helicopter will provide two types of service—quick intervention for trauma patients, as well as transfer of patients already undergoing general hospital treatment to facilities where highly specialized care is available.

In traumas such as traffic accidents, victims could be moved from the scene to the nearest appropriate medical facility.

Life Flight is as well equipped as a typical hospital emergency department, so that sophisticated care begins as soon as the jet helicopter lands at the scene, said Eliastam. The crew, in addition to a pilot, always includes a flight nurse and physician specially trained in trauma care.

Filgas noted that Queen of the Valley Hospital in Napa, a 25-minute helicopter trip from Lakeport, is the designated trauma center for the area, "and we expect that many of our trauma patients will be taken there." She said some cardiac patients might be transferred to St. Helena Hospital.

Eliastam said he expected that a majority of the patients transferred by Life Flight would remain in Lake, Mendocino or surrounding counties.

"We are anxious to maintain traditional referral patterns in these communities," said Eliastam. Life Flight, since its inception by Stanford and SCVMC in May 1984, has made more than 350 emergency flights.

In addition to general trauma aid, the helicopter can offer rapid transport dispatch for patients when a specialized facility is required. For example, burn and spinal cord injury patients can be transferred to SCVMC's burn unit, Filgas said.

Highly specialized care in a university setting is available in less than an hour at either Stanford or the University of California, Davis. Eliastam said patients might be transferred to SUH for highly sophisticated intensive care, replantation surgery (such as reattaching fingers), neurosurgery, pediatric surgery or complicated cardiovascular surgery.

"Patients already receiving intensive care in a local hospital can continue to receive physician and nurse monitored care enroute to a specialty hospital," Filgas explained.

The second helicopter, said Gomez, provides a research institution an opportunity to study the patterns of emergency medical needs in a rural area. Meanwhile, said Filgas, the medical community around Lakeport has been given an opportunity to establish a working, learning relationship with an academic medical institution.

Life Flight may be contacted at (415) 497-5578.

LEADERS, RESEARCHERS CRITICIZE FACILITY INSPECTION BILL

STANFORD—

A bill expanding the inspection powers of private groups "invites a vigilante approach to monitoring research laboratories," a Stanford official said Thursday (June 27)

Dr. Lawrence G. Crowley, vice president for medical affairs at Stanford, is among California medical school leaders opposing Senate Bill 1405, sponsored by state Sen. President Pro Tem David Roberti, D-Los Angeles.

Crowley said he believes that inspection of biomedical laboratories where animals are used "is the responsibility of federal and state government, not private organizations with little accountability to the public."

SB 1405 would expand law enforcement powers of privately appointed officers in California to federally-licensed biomedical research facilities. These facilities, including Stanford and other medical schools in California, are regulated by the federal Animal Welfare Act.

The United States Department of Agriculture (USDA) is responsible for inspecting these research facilities and is mandated to make unannounced inspections. Humane officers may enter only with the permission of the institution or with a warrant. SB 1405 would grant humane society officers entrance without a warrant for unannounced inspections to these federally-regulated facilities.

The bill passed the state Senate 21 to 11 on June 18 and is currently pending in the assembly. If it passes there, it would go to the governor for signature.

Senate Republican leader Jim Nielsen of Woodland opposed the bill on the senate floor.

"What we don't need is more amateur law enforcement in this state," Nielsen said later.

Another legislator, Sen. Walter Stiern, D-Bakersfield, a practicing veterinarian for 24 years, called SB 1405 "an attempt by persons who have misplaced feelings to expand a mechanism that is misguided and not needed. It will ultimately harm law enforcement and medical progress in this state while accomplishing nothing of value for animals," Stiern said.

"This moves away from a long established trend toward professionalized law enforcement in this state," said Marvin Herrington, chief of the Stanford University Police and a reserve captain in the Santa Clara County Sheriff's Department.

"It grants enormously expanded powers to nonprofessional persons in an arena where a great deal of technical and legal expertise is required. Also, it sets up a category of law enforcement officials which are answerable to a private corporation, not to an elected body. For example, there is no requirement that these new enforcement officers even be deputized, bonded or insured."

In Southern California, Albert A. Barber, vice chancellor for research programs at UCLA, said, "It is important that appropriately trained federal and state employees have the resposibility for inspecting our animal research facilities. However, Senate Bill 1405 would permit untrained individuals to assume this complex responsibility.".

Crowley said, "this bill would permit a group vehemently opposed to animal research under any circumstances to designate any number of humane officers to 'ensure compliance' with complex federal laws pertaining to research," said Crowley.

6/27/85 -more-

"It is clear that biased or uninformed humane officers outside the mainstream could disrupt important medical research.

"We have already seen incidents throughout the state and nation of important research stopped by vandalism of facilities and harassment of scientists and health workers by irresponsible individuals who would gain legitimacy through this ill-conceived legislation. SB 1405 invites a vigilante approach to monitoring research laboratories because it expands police powers indiscriminantly and unprofessionally.

"While the controversy about the use of animals in research has existed for more than a century, the public through its elected representatives has always chosen to continue and support biomedical research. Government has been the impartial agent of the public to regulate and oversee the research to ensure that animals are properly treated and that the public welfare is served," Crowley said in a statement.

"Enforcement of applicable federal laws and rigorous standards of humane care are important objectives," Crowley continued. "But enforcement must come from fair, impartial and qualified inspectors.

"While some existing humane societies might indeed endeavor to provide fair and competent inspections, the reality is that SB 1405 makes no distinction between reasonable enforcement and blatant harassment.

"It might be useful to draw on the expertise available from humane groups at some point, but we would hope that this support would come in the context of professional veterinary care, not an adversarial relationship," Crowley said.

The vice president said institutions such as Stanford have made major strides in recent years to improve animal care and ensure safeguards for humane treatment. At Stanford a $12 million state-of-the-art animal care facility is about to open, and a committee which reviews care and experiments has recently been expanded by adding more non-Stanford members, including a veterinarian outside the research community.

ANTI-CANCER ANTIBODY RESULTS ARE ENCOURAGING BUT MIXED

STANFORD—

Stanford University Medical School doctors who four years ago pioneered the experimental use of monoclonal antibodies to treat cancer, this week reported "encouraging" but mixed results in an extended series of patients with lymphoma, cancer of the lymph glands.

In two articles, published in the June issue of the medical journal *Blood* and in the June 27 issue of the *New England Journal of Medicine*, the scientists outline their results in 11 patients, describe why the experimental therapy sometimes fails, and suggest ways to overcome the complications.

The overall outlook for monoclonal antibodies in cancer treatment is promising, they predict, particularly as researchers learn more about which patients are likely to achieve the best response, and how to modify the treatment to get the maximum anti-cancer effect.

Antibodies are disease-fighting proteins made by the body that can be targeted to recognize specific substances or cells.

Four years ago, the Stanford team treated their first patient with the experimental therapy. That 67-year old man whose cancer was growing at the time had a complete remission of his disease. Since then, ten more patients have been treated and although four of these have had beneficial effects, none has shown a complete disappearance of tumor like the first patient.

"We are just beginning to realize why some patients respond to the treatment better than others," said Dr. Ronald Levy, the Stanford oncologist who leads the research.

"Also, we now know why some tumors do not respond completely," he said.

In the study reported in the *New England Journal of Medicine*, the Stanford team discovered that tumors contain rare mutant cells that can escape the effects of the treatment and give rise to a new tumor.

Based on this finding and their experience with the first 11 patients, the researchers have already made an important modification to their treatment plan that they believe will improve its effectiveness.

The researchers plan to administer more than one monoclonal antibody, each tailored to attack a different cell population present in the patient's tumor.

"It's the same idea as using multiple drugs to treat infectious diseases," Levy said.

In the same way that multiple drugs have a better chance of controlling a disease if the infectious agent becomes resistant to a single drug, multiple antibodies may be more effective against cancer than a single one, he explained.

Levy thinks there will be a role for the specialized antibody proteins in combatting B-cell lymphomas, cancers of the body's white blood cells.

The approach may also be of benefit in other types of cancers involving the white blood cells known as T-lymphocytes, although the researchers are only just beginning to explore this possibility, Levy added.

The *Blood* article outlining results in 11 patients was written by Drs. Timothy Meeker, James Lowder, David Maloney, Richard Miller, Kristiaan Thielemans, Roger Warnke, and Levy.

6-26-85 -more

The *New England Journal of Medicine* article, which describes two patients whose tumors escaped effects of the antibody therapy, was written by Drs. Meeker, Lowder, Michael Cleary, Stanford Stewart, Warnke, Jeffrey Sklar, and Levy.

The research program is funded by the American Cancer Society and the National Institutes of Health.

To deploy monoclonal antibodies against cancer, Levy and his colleagues prepare the protein molecules in the laboratory for each patient. The antibodies are custom-tailored to specifically recognize the patient's own tumor cells.

It is possible to target antibodies specifically against cancer cells if the cells have a specific "marker" protein the antibodies can be aimed at, Levy explained. B-cell tumors, whose cells all produce a specific antibody molecule, have precisely this characteristic, he said.

Five of 11 B-cell cancer patients—all of whom had failed to respond to conventional anti-cancer treatments such as drugs and radiation—experienced at least a 50 percent shrinkage of their tumors and one patient had a 40 percent shrinkage after injections of the special antibodies, the scientists reported. However, tumors in four of the patients returned within one to six months after the treatments, they added.

In another five patients, the experimental therapy produced no clinically significant effects, although one patient died of complications of his tumor before a clinical response would have been expected, the doctors said.

A fifty percent response rate for a new form of treatment is quite encouraging, Levy suggested, particularly in a group of patients with advanced disease who had previously failed to respond to conventional forms of anti-cancer therapy.

The most complex problem arose when the tailor-designed anti-cancer proteins failed to completely eradicate all tumor cells, allowing the cancer to regrow.

Levy and his colleagues believe that in at least two of their patients and probably more, this occurred because of mutations—slight variations—in the marker proteins of a small number of cancer cells.

The highly targeted monoclonal antibodies helped kill off the majority of cancerous cells but failed to recognize the variant tumor cells, the scientists believe.

Although only a few camouflaged cancer cells might escape the antibody therapy, these could then quickly regrow into a new cancer.

Levy and his colleagues believe they will be able to surmount this problem by preparing multiple anti-tumor antibodies for each patient, targeted to recognize all the variant cells of which the tumor is composed.

Levy said that the researchers are trying to develop a way of predicting which patients stand the best chance of being helped by monoclonal antibodies. Some evidence suggests that it may be those people whose immune systems are already mobilized to fight their tumor.

Monoclonal antibodies alone don't kill tumor cells, he explained, but they help induce the patient's own immune system to fight the tumor.

SOCIAL WORKER AARON SMITH HONORED WITH AWARD, PROMOTION

STANFORD—

Aaron Smith of Stanford University Hospital's department of clinical social work is the recipient of the 1985 John B. Harris Award from University of California, San Francisco.

Smith, who earned his Ph.D. in medical sociology from UCSF's School of Nursing, received the award for "best exemplifying the qualities of the late teacher, physician and civil rights advocate."

Smith is the seventh recipient of the award. He received $400 and an inscribed scroll. His name will be engraved on a plaque with other award recipients.

Smith, who was recently promoted to assistant director of the hospital's department of clinical social work, has been at Stanford since 1969. He is a supervising clinical social worker in charge of the cardiology team, and works primarily with patients in pediatric cardiology and cardiovascular surgery. In his new position he will be responsible for all teaching and research activities of the department and will assume the director's duties in her absense.

Smith is also a lecturer in Stanford's department of family, community and preventive medicine, a visiting lecturer for the American Cancer Society and a field instructor in hospital settings for second year students at University of California, Berkeley.

Smith has conducted a four-year American Cancer Society study on the impact of leukemia on the family unit and a two-year Stanford study on what role the family plays in children with Down's Syndrome who survive open heart surgery.

Smith holds a masters of public health degree from UCB, a masters of social work degree from Howard University and a bachelors degree in psychology from Florida A. & M. University.

SPELLING DEFICIENCIES TURN TO SUCCESS FOR SEMI-RETIRING ADMINISTRATOR

Eds: Photos available on request

STANFORD—

Her career at Stanford University having flourished to a peak after a rocky beginning 17 years ago, Rosemary Hornby now looks forward to semi-retirement as a time to share with others some of the knowledge she has gained.

Hornby is about ready to shift from her full-time career as manager of the medical school's Human Resources Group (HRG) to a semi-retirement slot as director of training for the 1,400 non-faculty staff members in the Stanford University Medical School and Clinic.

The seven-person HRG, which Hornby, 62, heads and where she will continue to work 50 percent time, is the only office concerned solely with the medical school and clinic's non-faculty employees. Its duties range from job classification and pay under the university's recently decentralized system, to employee events and courses.

"We are continuing to search for a replacement for Rosemary, and it is not an easy task," said David Mendelow, associate dean for administration at the medical school. "Rosemary has a particular style—a great deal of grace along with the ability to be firm and consistent with a huge number of constituencies. She has unique 'people' skills, and finding the right person to replace her is quite difficult."

Hornby credits her professional growth in great part to a Stanford personnel policy which she said attempts to creatively match people with their jobs. It is not coincidence that her own job has turned into a primary force behind that policy.

When Hornby first joined Stanford in 1968, she was recently divorced with two children, and as she put it, "I needed the money."

She had worked at jobs, including several years of increasing responsibility as a research assistant at Mills College before she was laid off. But Hornby needed a steady paycheck when she walked into the political science department for her first day as a secretary.

"I bombed out," she recalled in a recent interview. "I couldn't spell and I couldn't type."

Arlee Ellis, the department administrator then and now who hired Hornby, agreed with the evaluation but felt strongly that she shouldn't let this new employee walk away with a sense of defeat—not only for Hornby's sake but because Ellis sensed this new employee had something potentially valuable to offer Stanford. Ellis asked the personnel office to try and find something for her.

Hornby was hired as an administrative assistant in the medical school, processing personnel forms to ensure that funding for each position was available. Her role gradually increased as she took on additional responsiblity for reviewing hiring decisions.

There was no typing and no critical need for spelling skills, said Hornby, and the job offered an opportunity in a specialized area to learn the burgeoning array of new federal anti-discrimination regulations which were becoming an increasingly crucial component of the hiring and termination process.

"People started to rely on the information I was able to pick up, and my responsibilities continued to increase." By 1972, Hornby had been promoted to administrative assistant II. "I thought I had it made," she said.

"I had never seen myself as an administrator but I was really enjoying the work," she said.

"In effect, I created my own job growth by identifying areas that needed doing and problems that needed to be solved. Later someone would look around and find that my job classification didn't match the increased responsibility. You can't just sit back and expect other people to give you more work and more responsibility," she said.

Gradually she became a resource on a wide variety of personnel issues. In 1976, she was named an administrative service manager, and, three years later, was given her most recent title. Over the years she had made the transition from homemaker to breadwinner and then to successful executive. Hornby, perhaps predictably, said the increased responsibility she received wasn't just luck.

"It was a combination of being in the right place at the right time, curiosity, and liking what I was doing," she said.

Other people agree.

Rob Parker, the university's director of personnel, said Hornby has effectively built her career around relationships in the workplace and an intimate knowledge of the institution's objectives and missions.

"She established relationships and credibility with faculty and staff, and people began to gravitate to her to solve problems and get things done," said Parker.

He said her approach is a nice blending of understanding and appreciating both the employee and employer needs to effect solutions to problems without simply invoking regulations or bureaucratic procedure.

"She's gracious, yet powerful," he said.

Hornby said she sees her function and that of human resources as that of problem solver, one who can overcome the oft-stated attitude, "You can't do that."

A typical problem was how to develop a job description and salary level for a position in an academic division that needed an administrator with engineering background. Another challenge was to properly classify an employee who spent most of her time doing office assistant tasks but occasionally was thrust into the role of dispatcher for the center's pediatric transport service.

In her new role, Hornby said she hopes to be able to pass along some of the things she's learned about how to succeed in the university environment by offering career counseling as well as augmenting the personnel courses currently on the books.

Of particular interest, she said, is establishment of short, specific courses which will teach employees, including managers and perhaps even faculty, skills they need to function effectively as supervisors and administrators.

For example, she is interested in conducting sessions on how to check references—"not the theory, but a step-by-step rundown of what questions can and should be asked and how to interpret the answers."

Counseling, she said, could take on the role of helping persons "find the right situation in the university. There are a lot of talented people whose careers, like my own many years ago, are threatened because they are in the wrong job."

Hornby said she would like to explore ways to provide more assistance to faculty who suddenly find themselves managers.

Not all of the experience she hopes to pass on was garnered on the job at Stanford. A fundamental lesson, she said, she learned on a summer job away while still a Stanford undergraduate in the early 1940s.

Hornby was working as a desk clerk in Yosemite National Park's Curry Village.

"A family was about to check in, and my boss informed me that he had had to substitute their long-requested reservation with an alternative. As my boss fled out the door, he told me:

" 'Rosemary, not only are you going to tell them about the change—you're going to make them like it.' "

ADVANCE FOR RELEASE FRIDAY, JUNE 21, 1985

MODIFIED CANCER DRUG—STILL ONLY EXPERIMENTAL—MAY BE MORE POWERFUL WITH FEWER SIDE EFFECTS

STANFORD—

Laboratory tests of a new anti-cancer agent that is at least two years away from clinical trials, suggest that it is less toxic and 500 to 1,000 times more powerful than most presently available anti-cancer drugs, according to a report in the June 28 issue of *Science* magazine.

But a Stanford University researcher who is studying the experimental agent in his laboratory cautioned that it is far too soon to know if the drug might some day be valuable against cancer in people.

At this early stage in the drug's development it still requires further laboratory and animal testing, and "it is probably at least two years away from clinical studies in humans," stressed Dr. Branimir Sikic, assistant professor of medicine (oncology) at Stanford University School of Medicine.

"It is an exciting new drug that is very promising for clinical trials in the future but at this point we don't have a new drug for patients," Sikic said.

The drug, called MRA-CN, was first synthesized three years ago by Dr. Edward Acton of SRI International in Menlo Park, Sikic said.

The average time it takes for a new drug to go through safety testing is five to seven years, he explained. Thus far the drug's effects have been studied in mice with tumors, with mixed results, and in cells taken from patients with cancers of the breast and ovary.

Some of the studies were sponsored by a grant from the National Cancer Institute administered through the Northern California Cancer Program, Sikic said.

The *Science* report on the drug's effects in cultured human cancer cells was written by Sikic, Acton, and colleagues Mohamed Ehsan, Dr. W. Graydon Harker, Nina Friend and Dr. Byron Brown of Stanford University School of Medicine; Dr. Robert Newman from M.D. Anderson Hospital in Houston; and Dr. Miles Hacker of the University of Vermont.

MRA-CN is chemically related to adriamycin, generically known as doxorubicin, the leading drug applied against a broad spectrum of cancers, including lymphomas, sarcomas, breast cancer, lung cancer, and cancer of the ovaries and uterus, Sikic said.

For many years researchers have been trying to chemically modify adriamycin and related drugs in order to design an agent with fewer side effects while retaining the anti-tumor effect, Sikic explained. This is one of the first such compounds to show promise, he said.

When the scientists compared the abilities of MRA-CN and adriamycin to prevent growth in cells from nine different human tumors, they found that the potency of MRA-CN ranged from 100 to 15,000 times that of the standard drug.

In another test they found that MRA-CN appears to lack one of adriamycin's most severe limitations, which is its tendency to destroy heart muscle cells, Sikic said. Above a certain cumulative dose, which is usually reached after six to nine months of therapy, patients have to discontinue adriamycin in order to minimize heart damage, even though the drug may be working against their cancer, Sikic said.

MRA-CN, on the other hand, appears not to damage heart tissue at doses which kill cancer cells, Sikic said. When the researchers administered the agent to cells from the hearts of fetal mice, cardiac toxicity was observed only at doses which because of its potency would be several hundred times those needed for a therapeutic effect, Sikic said.

MRA-CN also was effective in halting growth of cancer cell lines that had become resistant to adriamycin, he added.

"These studies demonstrate a clear separation of the anti-tumor and cardiotoxic actions . . . and also suggest that MRA-CN may be active against some human cancers which are resistant to doxorubicin," the researchers said.

Sikic said that MRA-CN's properties make it an attractive candidate for new "targeted drug delivery systems."

One such system under development is called liposome packaging, in which tiny membrane spheres containing drugs are aimed at specific targets, such as tumors, in the body. It is possible to make the spheres home in on specific targets by attaching them to monoclonal antibodies, proteins that are designed to recognize specific "addresses" in the body.

The advantage of such a system might be that the drugs are directed only against diseased tissues while normal tissues are spared from toxic effects, Sikic said.

Sikic's laboratory is collaborating on these studies with Drs. Demitrios Papahadjopoulos and Kate Mathay at the University of California, San Francisco, he said.

Sikic's lab is also studying how MRA-CN acts to halt cancer cell growth. Most cancer drugs work by blocking synthesis of DNA, the cellular hereditary material. This makes the drugs toxic not only to rapidly dividing cancer cells but also to other rapidly growing tissues in the body such as bone marrow.

MRA-CN may act to prevent DNA replication by two different mechanisms, Sikic said, which could be one explanation for its unusual potency.

KENNEDY ANNOUNCES REORGANIZATION OF MEDICAL CENTER

STANFORD—

President Donald Kennedy Tuesday, June 18, announced a reorganization of the Stanford University Medical Center administration to be effective January 1, 1986.

Under the new structure, the heads of the two largest components, School of Medicine and Stanford University Hospital, will no longer report to a vice president for medical affairs. That office will be discontinued when Dr. Lawrence G. Crowley, vice president for medical affairs and president of the Stanford University Hospital Corporation, retires at the end of 1985.

Dr. David Korn will hold a new title of vice-president and dean of the School of Medicine, and Sheldon S. King will become chief executive officer of Stanford University Hospital and president of the hospital corporation.

Korn, formerly chairman of the department of pathology, was appointed dean of the School of Medicine in October 1984. King has served as executive vice president and director of Stanford University Hospital since 1981, coming from the University Hospital and Clinics of the University of California, San Diego.

Presently, they both report to Crowley. He was the first executive to hold the vice presidential post when it was created in 1980 to meet special needs of the center. These included greater autonomy of the hospital, a restructuring of the faculty practice program, and the launching of a large-scale building program.

As vice president, Korn will be a member of the university's administrative council, thus providing important coordination between medical school programs and other parts of the university. On academic matters, Korn will report to the vice president and provost.

The vice presidential title for the dean, Kennedy explained, recognizes the varied responsibilities of the job. "Especially important are the medical school's interactions with affiliated hospitals, voluntary faculty, the community and Stanford University Hospital. That relationship is critical to each of the school's missions," he said.

King will report to the chairman of the Stanford University Hospital board of directors. Kennedy chairs the hospital board.

"The complexity of the hospital, its external relationships, and patient-care responsibilities seem to me to require a somewhat greater degree of independence than it has had in the past," Kennedy said.

Under the new arrangement Korn and King have also agreed on a plan of expanding the role of the existing medical center coordinating council.

6-18-85

-more-

Several important functions, Kennedy said, "require coordination across the medical center. They include development (fund-raising), public affairs, and center matters related to planning, administration and finance. Over the summer, I will consult with other vice presidents and with medical center staff to work out more precise administrative arrangements for the management of these functions."

Kennedy said he acted on the recommendations of a committee, headed by Vice President and Provost James Rosse. He also consulted with other individuals who provided "extremely thoughtful views."

The Rosse committee was asked last January to study the medical center's administrative structure in view of Crowley's impending retirement.

"Under the leadership of Larry Crowley, the vice presidency for medical affairs has been very successful in establishing coordination and in providing sound leadership," Kennedy said. "With unusual and able leadership in both the school and the hospital, it is not unreasonable to suppose that other modes of providing coordination might be equally effective.

"I have become convinced that the present leadership of the school and the hospital can work together in a coordinated fashion without there being a separate vice president for medical affairs."

Kennedy, however, left open future options. "Dr. Korn and I have agreed to review the situation at the end of 1986, to determine whether there is reason, based on the coordination of medical center affairs, to alter the administrative structure of the center," he said. "If at that time there appears a need for a separate dean and vice president for medical affairs, a decision on how to fill those two positions could be made then, with the benefit of a year's additional experience."

MEDICINE AND FILMMAKING PAVE WAY FOR 'UNIQUE' CAREER

STANFORD—

When Joseph Sachs entered Stanford medical school, he knew he was on his way toward his goal of becoming a doctor. He pushed aside his lifelong fantasy of becoming a filmmaker, however, thinking it would never be realized.

Six years later, Sachs is leaving Stanford with both an M.D. and an M.A. in filmmaking. His track record in both professions proves that medical students do not have to fulfill the stereotype of "eating, breathing and sleeping" medicine. Sachs was honored at Sunday's convocation with a research award for "outstanding achievement." And thanks to the filmmaking program, he has three films—and three awards—to his name.

"Stanford provided me with the perfect opportunity to pursue both fields," Sachs said. "I couldn't have done it anywhere else."

Despite joshing by friends that he will drop out of medicine and pursue filmmaking fulltime, Sachs plans to combine the two to make what he considers a unique contribution. He'd like to achieve two things with his dual expertise: demystify science for the lay public and improve medical education.

Towards these goals, Sachs' first film, "Just What *is* DNA?"—for which he won awards at the Birmingham International Educational Film Festival and at the National Educational Film Festival—coaches viewers through 15 minutes of the ABC's of deoxyribonucleic acid, the grand chemical of genetics.

His latest project hits on one of his soapbox topics: ways to improve medical education. Entitled "Between a Rock and a Hard Place: Values, Ethics and the Physician-In-Training," the film consists of four 5-minute vignettes that point out many conflicts and dilemmas medical students confront during their clinical training.

Issues such as honesty, confidentiality, informed consent, rational decision-making, quality and dignity of patient care and teamwork among health care workers surface during the "trigger" films, so-called for their purpose of prompting thought and discussion among viewers.

Deans, ethicists and educators from medical schools throughout the country reviewed the scripts for Sachs' film, which was produced with funding from Squibb Co. through the American Medical Student Association and the Henry J. Kaiser Family Foundation. San Francisco director of photography Peter Thomas donated his services to the project, as did many local film industry members.

"People would always be blown away when I would say I was working on a film about ethics," Sachs said. "But we're not talking about the two-babies-and-one-respirator type of dilemmas. We're talking about day-to-day common events that people should be thinking about. For example, how common is it that a pack of doctors discuss a patient at the foot of the bed and act as if the patient isn't there when it would be just as easy for the pack to step outside the door?

"I'm hoping that after seeing these films, students will be better prepared to react if they disagree with a decision of a resident or an attending physician," Sachs continued. "Medical education as it is today prepares students to deal with the scientific aspects of treating disease and making diagnoses, but there is little preparation for dealing with the psychosocial side of medicine.

-more-

"Medical education is good, but it can be great," he said. "The challenge is to make it better."

Sachs has a lighter side to him as well, evident in his attempts to imitate filmmakers in his pinstriped seersucker jacket, light-colored slacks, bow tie, straw hat and wire-rimmed glasses he wears on some behind-the-camera occasions. And then there's his third film, a 4-minute video parody called "Treat It."

Filmed for the medical school's annual faculty-student show in 1984, the parody of singer Michael Jackson's tune features Stanford faculty and students in a fast-moving rock video style. It too did not escape notice—the film won an award at the annual Palo Alto Film Festival earlier this year.

"That was just plain fun," Sachs said.

Sach's interest was not always in medical education. As an undergraduate at Yale, he was involved with basic laboratory research. "It was enjoyable but it wasn't satisfying something in me," he said. He came to Stanford with a new interest in public health education and preventive medicine. It was the experience of receiving a medical education that awakened his interest in the educational process itself.

"Learning how to think and solve problems is a part of medical education that is exciting to me, but it isn't always taught as well as it could be," he said. "And then there is the need to teach students how to act in their roles as physicians."

It's that acting quality that appeals to Sachs—an acomplished musician, juggler and magician—as well. "Some of the best teachers are great actors," he explained. The satisfaction gained from acting is similar to that he gets from making films.

"The wonderful thing about films is you work so many hours for each minute of film," Sachs said. "You pack all your creativity, energy and ideas into that one minute and it's preserved forever. It's permanent.

"Film work is every bit as hard and challenging as the work in being a medical student. But when you walk into a theatre where an audience is watching your film and you see their reaction, well, it's quite an experience."

Sachs is on his way to University of California, Los Angeles, Medical Center where he plans to train in internal and emergency medicine. And then what?

"I'm not sure where all this will take me," he said with a smile. "I'm just going to sit back and enjoy the ride for a while, and we'll see where I end up."

DUPERRAULT NAMED ASSOCIATE DIRECTOR OF CLINIC

Photos available if not included with story.

STANFORD—

Jane Duperrault has been named associate director of the Stanford University Clinic and Faculty Practice Program (FPP), announced Donald Tower, executive director.

Duperrault has served as FPP director of finance since March 1982, a position she will continue to hold in her new appointment, which was effective March 1, 1985.

In addition to many of her current responsibilities, Duperrault will assume primary responsibility for legislative analysis, the FPP Budget Committee, departmental administrative service manager liaison, University Controller's Office liaison, and various special projects.

As the second ranking officer in the FPP organization, she will also assume staff responsibility for FPP strategic planning and coordinate educational activities for FPP departments, Tower said.

Duperrault also served as acting director of data systems for the Clinic/FPP from July through December 1983. Before joining Stanford she held finance positions at the University of Michigan Medical Center in Ann Arbor, and the Manufacturers Bank of Detroit.

She graduated from American University, Washington, D.C., in 1975, and received a master's degree from the University of Michigan Graduate School of Business Administration, in 1981. Her M.B.A. is in finance and information systems.

The Clinic/FPP is the organized medical group practice of physicians who are on the faculty of Stanford University Medical School. Stanford's medical group practice is one of the largest in the country with 290 physicians.

PREVENT NUCLEAR WAR, STANFORD MEDICAL SCHOOL GRADUATION SPEAKER SAYS

STANFORD—

Stanford University School of Medicine's commencement speaker challenged the medical and scientific community to "prevent the final epidemic of nuclear war" in his address at the Sunday (June 16) afternoon ceremony held on the medical school's alumni green.

"The overriding problem facing humanity today is the threat of nuclear holocaust," said Dr. David Hamburg, president of the Carnegie Corporation of New York. "A new level of commitment of the scientific community is urgently needed to reduce the risk of nuclear war.

"This requires a mobilization of the best possible intellectual, technical and moral resources in a wide range of knowledge and perspectives," continued the former chairman of Stanford's psychiatry department. "A science-based effort is essential to maximize analytical capability, objectivity and respect for evidence—the outlook that is characteristic of the scientific community worldwide."

Hamburg spoke to graduates, families and friends gathered for the presentation of 156 academic degrees, including 78 M.D.s. Faculty awards and student research awards were also presented

While concerned primarily with the threat of nuclear war, Hamburg stressed that all technology developed over recent decades must be further evaluated for efficacy, safety and cost-effectiveness in health care. "Scientific assessment of medical technology and its uses is extremely limited at present," he said.

There must be, Hamburg continued, "a major increase of funding for research on health care—not instead of basic research—but rather building on the essential base of fundamental research that is now being so powerfully strengthened."

But the funding trend, he added, is leaning in favor only of research and development for defense.

"A look at total federal research and development for fiscal year 1986 compared to 1985 shows big increases in defense research and development, decreases in non-defense research and development, and virtually flat basic research," Hamburg said.

Such clinical research involving medical technology assessment has not had a high priority in the past, Hamburg said, and poses "formidable clinical, methodological, logistical, ethical and financing problems." It's essential, however, because it provides a significant link towards improving health care in the future.

"The crucial integrative task is to foster innovation and provide adequate asessment as rapidly as possible when innovation is applied to health care," he said.

The ideal place for this type of clinical research is university-based health centers, Hamburg continued. It's important to examine how to organize the functions of academic medical settings to encourage such research, and how to combine the expertise of other disciplines—engineering, statistics, social sciences—in research assessing technological innovations.

The unprecedented technological innovations that have occured over recent decades have been used both for better and for worse, Hamburg said. "While we take pride in our accomplishments, we must seek to make better use of them to relieve human suffering and improve chances for a decent future."

FACULTY, STUDENTS HONORED AT STANFORD MEDICAL GRADUATION

STANFORD—

Awards were presented to 14 faculty members at Stanford University School of medicine's convocation ceremony Sunday (June 16).

Dr. Harry Oberhelman, professor of surgery, received the Alwin C. Rambar Award for Excellence in Patient Care.

Receiving the Arthur L. Bloomfield Award in Recognition of Excellence in the Teaching of Clinical Medicine were Dr. Robert Sladen, assistant professor of anesthesia, and Dr. Ross McDougall, associate professor of radiology.

The Henry J. Kaiser Family Foundation Award for Outstanding and Innovative Contributions to Medical Education was awarded to two faculty members: Dr. Kelley Skeff, assistant professor of medicine and Dr. Robert Cutler, professor of neurology. Cutler is associate dean for faculty affairs.

Drs. Paul Basch, professor of family, community and preventive medicine; Charles Carrington, associate professor of pathology; Robert Chase, professor of surgery; and Charlotte Jacobs, assistant professor of oncology, received the Henry J. Kaiser Family Foundation Award for Excellence in Preclinical Teaching.

The Henry J. Kaiser Family Foundation Award for Excellence in Clinical Teaching was awarded to Drs. Nirmala Bhat, clinical assistant professor of gynecology and obstetrics; Ira Greene, physician specialist in dermatology; Henry Jones, professor of radiology; Teresa Ponn, clinical instructor of surgery; and Chris Snow, physician specialist in general internal medicine.

The final graduating class in physical therapy presented the Lucille Daniels Recognition Award for Outstanding Contribution to Physical Therapy at Stanford to Dr. John Medeiros, director of the program.

Meanwhile, 16 graduating medical students received outstanding acheivement in research awards. They were Graham Barnard, Paul Berger, Peter Brett, Randy Bucalo, Irving Kaplan, Susan Knox, Frank Lexa, Charles Link, Michael Mai, Jane Marten, Linda Meier, Tien Pham, Daniel Rubin, Reid Rusamen, Joseph Sachs, Stephen Salloway, Gary Schwartz and David Wexler.

Three other medical graduates—Rona Giffard, David Maloney and Kevin Roth—were recognized for their participation in the Medical Scientist Training Program.

VOLUNTEERS NEEDED FOR LUNG STUDY

STANFORD—

The division of respiratory medicine at Stanford University Medical School is seeking healthy, normal volunteers for a painless, non-invasive study to access normal airway function.

The results will be used to compare normal lung function with that of heart-lung transplant patients.

Selected volunteers will spend a total of about three hours at the medical center. Benefits to participants include a free pulmonary function test and lung evaluation.

Excluded from the study are people with personal or family history of asthma or allergies, and persons who have had a cold or flu in the past two months.

For further information or to volunteer, call James Harvey at (415) 497-6381.

MARIAN KNOX APPOINTED ASSISTANT DEAN FOR FACULTY AFFAIRS

STANFORD—

Marian Knox has been promoted to assistant dean for faculty affairs at Stanford University Medical School, announced Dean David Korn.

"I was really pleased to learn of the promotion," Knox said. "I'm looking forward to working with the deans of the medical school in my new position."

Knox had served as assistant to the associate dean for faculty affairs since 1973.

"Knox brings to the job considerable finesse in what can be difficult personnel problems," said former associate dean of faculty affairs Dr. John Wilson. (Dr. Robert Cutler succeeded Wilson, now professor of sugery emeritus, earlier this year.) "She's a tremendous asset to the deans and department chairmen of the medical school."

As assistant dean, Knox is responsible for "facilitating" faculty appointments, promotions, salary determinations, sabbaticals and other related issues. It is her job to obtain and organize required documentation for any faculty position changes before it is sent to the University provost for review.

Knox is also the staff person who arranges schedules for and takes minutes at major school committee meetings. In this capacity, Wilson said, the medical school deans, associate deans and other committee members call upon Knox's broad knowledge of medical school and university rules and policies concerning any proposed actions.

"One of her many strong points is that she works extremely well with other people," Wilson said. "In her position, that's key."

Knox is a graduate of Northwestern University. Prior to joining the medical school staff she held posts at Stanford's engineering school and at University of Chicago Hospitals and Clinics.

PHYSICAL THERAPY PROGRAM TO GRADUATE ITS LAST CLASS

Photos available on request if not included with story.

STANFORD—

Stanford University's physical therapy program will graduate its final class June 16, 1985, during the School of Medicine's convocation ceremonies.

The nationally recognized, 63-year-old physical therapy program will be terminated effective Aug. 31, 1985, because of a change of academic priorities as well as fiscal constraints in the medical school.

Students, alumni and faculty of the division held a "last dance" reception here Saturday, June 1.

"I believe the years ahead hold many opportunities in the field, and that we'll be all the better for having weathered this storm," said Dr. John Medeiros, acting director of the division since 1982, in comments to the crowd.

The 30 graduating students of the class of 1985 organized the event, partly as a fund raiser for the Foundation for Physical Therapy Education and Research, a group formed by Medeiros and lecturer Wendy Mason in response to the closing of the division at Stanford.

"This is our last get-together to talk about future and past directions for physical therapy," said student Erica Gould, chief organizer. Most of her fellow classmates from the two-year master's degree program, Gould said, will be looking for jobs all over the country after taking their board examinations July 19 in Los Angeles.

"Today we're at a crossroads," continued Medeiros, an assistant professor of physical therapy. "But our commitment to learning unites us. I like to think of physical therapy as a synthesis of caring and learning."

The final decision to end the program at Stanford was made in November 1983 by Albert Hastorf, vice president and provost of the university. Hastorf said he had reached his decision "reluctantly" after committee review because physical therapy was clearly a program of quality and its graduates are highly respected, occupying faculty posts in more than 40 percent of the schools of physical therapy in the nation and directing 17 percent of the programs.

"It's never easy to terminate programs that have embodied a worthy cause," Dr. Dominick Purpura, medical school dean at the time, had commented. "But budgetary constraints are becoming severe. Everything the medical school does must have a clear relationship to its core academic programs."

6-11-85

-more-

The physical therapy program was established in 1922, just one year after the American Physical Therapy Association formed. It was based at Stanford University Hospital on Clay and Webster Streets in San Francisco.

In 1940 physical therapy was transferred to the Stanford campus with facilities divided between the men's and women's gymnasiums. Catherine Worthingham—"a pioneering figure" according to Dr. Helen Blood, a physical therapy professor and herself an alumna of the program—was director.

The program moved to what was then known as the Stanford Village in Menlo Park in 1946, and it became technically a part of the School of Education. It was housed in Stanford's emergency housing project which was formerly the Army's Dibble General Hospital.

Faculty included Lucille Daniels as director, and the late Dr. William Northway, professor of physical medicine in the medical school.

With the outbreak of the polio epidemic in the mid-forties physical therapy gained prominence as the Polio Epidemic Unit to send trained workers anywhere on the West Coast when polio outbreaks got out of control.

Much of program financial support was then coming from the National Foundation for Infantile Paralysis.

In 1955 on recommendation of Dr. Windsor Cutting, then dean of the medical school, the Board of Trustees transferred the physical therapy program to the medical school. When the school moved from San Francisco to the Stanford campus in 1959, the physical therapy division and the Stanford School of Nursing became a part of what was then envisioned as an expanding department of allied medical sciences, with the potential of added programs in the future.

This never became a reality. The School of Nursing was the first to be phased out in the mid-seventies because of new medical school directions and priorities.

In recent years the Stanford physical therapy program has included requirements for licensure, three advanced study areas and student research projects. It has offered an entry level master's degree for students beginning in physical therapy, and a post-professional master's program for physical therapists interested in pursuing advanced graduate work.

"There have been many highlights over the years," recalled Blood, citing, as an example, that "we were the first group to set up physical therapy in home care services in Santa Clara County."

Blood, a former director of the division, plans to take the summer off. Then she will resume work, hoping to teach and consult overseas.

Professor Barbara Kent will officially retire, although she is working on a book about the hand. She and Blood, the two senior faculty members, were made professors emerita last month. Kent was also honored and surprised at the event, when Blood presented her with copies of many letters from students, faculty and alumni supporting her nomination last year for the national Baethke-Carlin Award.

-more-

Other faculty members are still finalizing their plans.

Medeiros is interested in aerospace efforts to counteract muscle atrophy in astronauts.

Gail Jensen, physical therapy lecturer and a 1978 graduate of the division, is now a doctoral student in Stanford's School of Education. She plans to complete her dissertation in the fall, work as a clinician at Stanford Hospital, and then look for another teaching position elsewhere.

Kay Shephard, assistant professor, will move to Philadelphia as an associate professor at the School of Allied Health, Temple University. There she will direct graduate studies in physical therapy.

Ann Hallum, senior lecturer, is enrolled in the doctoral program in counseling psychology at Stanford. Her long-range goal is to combine both backgrounds, working with families of children who have physical problems or disabilities.

Mason has been named director of the cardiac rehabilitation center at Saddleback Community Hospital in Laguna Hills, Newport Beach. For the summer she will teach at the University of Texas. One of few physical therapists interested especially in cardiopulmonary aspects of recovery, she said she also hopes to remain in the teaching field.

Lecturer Emily Savinar will work as a clinical specialist in orthopedics at Kaiser Hospital in Oakland.

Dr. Martha Jewell, lecturer, will continue part-time teaching and enter private practice as well. Her specialties are neuroanatomy and pediatrics.

Sarah Semans, associate professor emerita, is currently working on a book on exercise for the elderly.

Three support staffers of the division are still looking for new jobs, with help from the medical school's human resources group, Medeiros said.

In addition to a donation from the physical therapy alumni club, money was raised at the last dance through the sale of alumni T-shirts with a design by student Devra Einkauf, showing the Stanford tree with a large branch symbolically broken off.

It was the second fund raiser held for the new Foundation. The first, Gould said, was aboard a yacht once owned by Julie Andrews, "The Tempest," at the St. Francis Yacht Harbor in San Francisco, May 11.

The Foundation was started, Medeiros said, as a strong, non-profit group outside the university to support continuing programs in the Bay Area as well as possibly to open a new one.

Nationwide efforts to focus attention on the contributions of physical therapy to improving the health of all Americans will take place during National Physical Therapy Week, June 16 through 22, this year entitled "Physical Therapy Promotes Healthy Aging." The week is sponsored by the American Physical Therapy Association.

AWARENESS OF CHILD ABUSE KEY TO GETTING HELP

STANFORD—

In compliance with a state requirement, certain health professionals now are required to sign a form acknowledging they are aware of and will comply with their obligation to report known or suspected cases of child abuse to a child protective agency.

"Our compliance with the new requirement is only part of our commitment to increase employee awareness of this problem," said Karen Axnick, who is coordinating implementation of the form requirement among Stanford University Hospital, Clinic, and Medical School employees hired after Jan. 1 of this year.

Axnick, director of Care Review/Risk Management, noted that "last year a multidisciplinary task force headed by the Department of Clinical Social Work developed Hospital guidelines for managing child abuse and neglect cases."

"We generally report two or three cases of child abuse each month," said Maria Nasjleti, clinical social worker at Stanford. "Most of those are children brought into the emergency room or clinic. They aren't always overt cases of abuse. Some are what appear to be accidental injuries that are actually a result of poor supervision."

She said summer is a time when these injuries are more common. "When people leave their windows open during the summer, they need to take extra care with their kids. We've had cases of children falling cut of second story windows or running into traffic. Kids need responsible supervision and sometimes the reason they aren't getting it is because their mother is unavailable or absent."

She spoke of one case that would come under a relatively new category of child abuse--"medical neglect." A one-year-old girl suffering from infantile asthma was admitted to Stanford with pneumonia three times over a three-month period. After each discharge, the mother had not brought her back to the clinic for follow-up checks and she admitted that she had not given the little girl her medication, Nasjleti said. Her reason was that she didn't have a ride to get back to the clinic or to go to the pharmacy.

"We felt the mother had no appreciation for the seriousness of her child's problem," Nasjleti said. "We reported the case to a child protective agency and they investigated. That child is now in a foster home."

Nasjleti stressed, "When a professional makes a report to the welfare department, it's not necessarily because the parent is abusive, and it's not a requirement that the child be removed from the parent's care. Often, the parent needs some assistance in terms of services to the family. They might need transportation services. They might need guidance in terms of child development, so they might be required to attend a parenting class, for example. Ultimately, the main thing we're concerned about is helping the child."

The intent of the state legislation is to strengthen the reporting system for child abuse which the legislature views as "...a serious problem, as evidenced by the fact that the number of cases reported to the Attorney General each year...has increased over 900 percent from 1974 to 1983."

"It's important for all employees, even those not specifically designated by the new law, to be aware of the need to report suspected cases," Axnick said. "Often the signs and symptoms are subtle, but alerting the proper authorities may literally mean the difference between life and death for an individual child."

Those required to sign the new forms are:

Medical practitioners, such as nurses and physicians, including house staff, emergency medical technicians and paramedics. Others include physical therapists, speech pathologists, pharmacists and clinical lab technicians. Also required to sign the form are psychologists, psychological assistants, dentists, dental hygienists, chiropractors, and optometrists.

Non-medical practitioners, such as marriage, family and child counselors, coroners, state or county public health employes who treat minors for venereal disease or any other condition; and religious practitioners who diagnose, examine or treat children.

Child care custodians, such as social workers, teachers, licensed day care workers, employees of child care institutions and probation office.

COLORFUL PIGMENTS FROM ALGAE BLEND MARINE BIOLOGY WITH MEDICINE

STANFORD—

Stanford and University of California scientists have turned colorful pigments from algae into molecular "tags" with widespread uses in medical diagnosis and research.

The pigments can substitute for many of the radioactive substances now widely used to identify specific cells or proteins, the scientists said.

When attached to cells or molecules, the brilliant blue and red pigments are like tiny fluorescent beacons that enable doctors or researchers to see substances even at very small concentrations.

Because they are not radioactive, the proteins are safe to use in research and clinical laboratories, the researchers said.

The fluorescent molecules have already been used clinically to screen donated blood for abnormalities such as AIDS, and to monitor blood levels of drugs such as digoxin in patients, according to Dr. Lubert Stryer, professor of cell biology at Stanford University School of Medicine.

A patent covering use of the pigments was issued last week by the U.S. Patent and Trademark Office in Washington, D.C., said Katharine Ku, associate director of Stanford's office of technology licensing.

The pigments, which have the tongue-twisting name of phycobiliproteins, were developed by Stryer and colleagues Dr. Vernon Oi, formerly a postdoctoral scholar at Stanford and now at Becton Dickinson Monoclonal Center, and Dr. Alexander Glazer, professor of microbiology at the University of California in Berkeley.

The development came about because Oi was looking for a tag that would fluoresce in the orange and red wavelengths, to extend the detection range of fluorescent markers already available, Stryer said.

Fluorescence happens when a substance gives off light of a particular color in response to being hit by incoming light of a different color.

At a New Year's Eve party, Stryer and Glazer discussed the problem and realized that phycobiliproteins, the subjects of Glazer's research, might provide the solution.

"We sketched out a research plan that night," Stryer recalled. It took only about six months to develop a useful product, the researchers reported.

The pigments fluoresce with 10 to 20 times the intensity of most other fluorescent labels, Stryer said, which makes them the first real viable alternative to high-sensitivity radioactive labels for spotting important cells or molecules that are now otherwise out of range.

"For instance, early detection of cancer is one possible application," Stryer suggested.

For diagnostic use, the proteins must be attached to the substance that is to be detected, forming what is called a conjugate, Stryer explained.

A conjugate can be formed with an antibody molecule—a protein made by the body's immune system that is targeted to recognize abnormal cells or substances in the body.

If the antibody is one that recognizes cancerous cells, then doctors might be able to detect the cancer at early stages by taking tissue samples and looking for the fluorescent tags under the microscope or with sophisticated cell-sorting equipment.

Conjugates formed with drugs are also useful diagnostic tools. One company has already developed such a test that uses a phycobiliprotein conjugate to track blood levels of the medication digoxin in patients, Stryer reported.

Antibodies and other specific proteins have been tagged by three phycobiliproteins so far, all fluorescing in the orange to red range, Stryer said. More are under development, he added.

Since the phycobiliproteins fluoresce in slightly different colors from one another when stimulated by a single beam of light, they can be used to track several different kinds of molecules or cells simultaneously, he added.

Phycobiliprotein pigments are manufactured by marine algae for use in photosynthesis, the process of converting sunlight into energy the cells need to grow.

The name comes from the Greek "phykos" which means seaweed and "bili" because the proteins are related to similar pigments found in bile.

Stanford has licensed the phycobiliprotein technology to Applied Biosystems of Foster City, which manufactures the proteins and provides the materials and sublicenses to other companies interested in the technology. Stanford has also licensed Becton Dickinson in Mountain View to develop phycobiliproteins for use in flow cytometric systems, Ku said.

TWO YOUNG PROFESSORS WIN PEW SCHOLARSHIPS IN BIOMEDICAL SCIENCES

STANFORD—

Two Stanford University assistant professors have been awarded $200,000 four-year biomedical research scholarships from The Pew Memorial Trust of Philadelphia.

Dr. Mark Davis, 32, assistant professor of medical microbiology, and Dr. Richard Scheller, 32, assistant professor of biological sciences, are among twenty "outstanding young medical researchers" selected for the 1985 Pew Scholars Program in the Biomedical Sciences, the Trust announced June 4.

The awards, presented for the first time this year, go to junior faculty members selected because of their outstanding promise in basic science or clinical research that will help advance human health, according to a Trust announcement.

Forty-four institutions were invited by the Pew Trust to nominate two candidates each for the 1985 scholarships. The recipients, chosen by a 13-member national advisory committee chaired by Rockefeller University President Dr. Joshua Lederberg, come from 17 medical schools and research institutes in the U.S., the Trust said.

Each scholar will receive a total award of $200,000 in annual stipends of $50,000 during the next four years, contingent upon progress toward stated research goals, the Trust said.

Both Davis and Scheller received their Ph.D. degrees from the California Institute of Technology in 1980. They worked in nearby labs at Caltech, and they have known each other and been friends for more than 10 years, Scheller said.

Davis was a postdoctoral fellow at the National Institutes of Health in Bethesda before coming to Stanford, while Scheller carried out postdoctoral studies at Columbia University prior to his Stanford appointment.

Davis is using modern molecular techniques, including recombinant DNA methods, to isolate genes that help control the immune system, the body's defense network against disease.

The major focus of his laboratory's research is the gene family that codes for receptor proteins on cells of the immune system. He and his associates were the first to find a T-cell receptor gene, one of the genes that codes for a protein involved in the body's ability to distinguish its own healthy tissues from abnormal cells and foreign tissues.

Among Davis' other recent honors are a Mellon Foundation Fellowship in 1983 and the 1985 Passano Foundation Young Scientist Award. He was also named one of the nation's top 100 young scientists by *Science Digest* last year.

Scheller has been using recombinant DNA techniques to analyze the nervous system of *Aplysia*, a dark brown sea snail that has only about 20,000 central nervous system cells.

His ultimate aim is to find out how genes are expressed in the nerve cells and eventually to understand what molecular changes occur in the nervous system to make learning and memory possible.

Scheller's other recent honors include a $500,000 Presidential Young Investigator Award, the Esther A. and Joseph Klingenstin Fellowship in the Neurosciences, and a Young Investigator Award from the Society of Neuroscience.

The Pew Memorial Trust is the largest of seven Pew Charitable Trusts, which support other programs in education, health sciences, culture, human services, public policy, religion and conservation.

EPIDEMIC ERADICATION EFFORTS HAMPERED BY LIMITATIONS IN RESEARCH METHODS

STANFORD—

Public health efforts against disease epidemics based on information from studies of laboratory-grown bacteria can be ineffective because of limitations in research methods, according to Stanford University Medical Center scientists.

"There is a fundamental problem in laboratory research," said associate professor of medical microbiology Abdul Matin. "Many public health and treatment decisions are made on the basis of laboratory findings. But these findings may not pertain to the actual behavior of the bacteria in a natural environment."

Legionnaire's Disease and other bacterial epidemics continue to break out despite attempts to eliminate them because of this problem, Matin said.

A series of articles, the most recent in the June issue of *Applied and Environmental Microbiology* show that laboratory-grown bacteria are much more susceptible to disinfectants and other treatments designed to eradicate them, while the same naturally grown bacteria resist the treatments and continue to thrive.

The studies were funded by the U.S. Environmental Protection Agency (EPA). Matin's collaborators include former graduate student James Berg, postdoctoral associate Steve Harakeh, Dr. John Hoff, EPA, and Paul Roberts, Stanford University civil engineering professor. The studies represent one of only a few attempts to look at bacteria in their natural state, Matin said.

The scientists reached their conclusions after studying a number of different bacteria, such as *Legionella pneumophila, Escherichia coli, Klebsiella pneumoniae and Yersinia enterocolitica*.

In order to grow bacteria quickly and in quantities large enough for research, scientists use a technique called "batch culture" in which the bacteria are given "superabundant" amounts of nutrients, Matin said.

These growing conditions differ greatly from those in natural environments, in which nutrients are nearly always limited and temperatures are not necessarily ideal. Bacteria grow at a much slower and lower rate because of these limitations, he explained. Using a device called a chemostat, the scientists were able to duplicate in the laboratory this aspect of bacterial growth in nature.

"The different concentrations of nutrients and different growth rates can greatly influence the composition of the bacteria," Matin said. These changes, he added, cause a difference "by orders of magnitude" in the sensitivity of bacteria to various disinfectant agents.

Specifically, the scientists have found that the make up of the cells' outer membrane changes significantly when grown under usual laboratory conditions. One protein, labeled *33 kDa*, on the surface of the bacterial cells completely disappears. Matin said they do not know why this happens. However, this change may be directly responsible in making the laboratory-grown bacteria much more sensitive to disinfectant agents such as chlorine dioxide and phenylphenol commonly used in bodies of water, air conditioning cooling towers and other places to prevent outbreaks of bacterial disease.

Bacteria grown in natural environments have the ability to adapt to a less-than-ideal situation, Matin explained. This makes them much more hardy.

"The whole question of whether or not to study microorganisms under conditions resembling nature has been shoved aside," Matin said. "But any study has got to be interpreted in a certain frame of reference. And if your frame of reference isn't right, the study is not worth as much as it could be."

Matin and his colleagues are now conducting further studies of bacterial composition under natural conditions in an effort to define the structural and physiological features that determine the ability of bacteria to cause disease. By doing so they hope to find a more effective way to help eliminate outbreaks of disease such as Legionnaire's Disease.

The most recent occurrence of Legionnaire's Disease was in Detroit in April, resulting in the death of at least one man and illness of at least 29 people after a hotel banquet.

The difficult-to-diagnose disease is symptomized by fatigue, muscle aches and headache. Fever, chills and sometimes abdominal pain follow.

Legionnaire's Disease was first identified in 1976 when 34 people died and 221 became ill during an American Legion convention in Philadelphia. The Centers for Disease Control estimate that about 25,000 people a year get Legionnaire's Disease.

FEARS AND PANIC CAN BE OVERCOME, PSYCHIATRIST SAYS

STANFORD—

Everyone has experienced fear at some time, but when fear becomes panic, it's time to seek help, says Dr. Stewart Agras of Stanford University Medical School.

Agras, director of the behavioral medicine program at Stanford, has written a book, "Panic" (pp. 151, The Portable Stanford and W.H. Freeman, New York, 1985, $11.95 paper; $21.95 cloth), to help the average person identify the point at which our fears stop protecting us from danger and begin to cripple us.

"The panic attack itself is only part of what for simplicity's sake we will refer to in this book as the panic syndrome," Agras writes. "The syndrome includes anxiety, phobia (particularly the limitation of mobility known as agoraphobia), isolation, and depression."

The professor of psychiatry says the details and extent of the development of the panic syndrome vary from person to person, but the first panic attack generally occurs in a public place.

"The victim of the attack suddenly feels ill, notices a fast and erratic heartbeat, experiences a tight feeling in the chest, breathes rapidly, and may feel faint," Agras says. "The rapid breathing leads to chemical changes that cause tingling in the hands and feet, numbness around the mouth, and dizziness.

"Nausea, headache, and stomach cramps may also occur during the attack. Often the physical symptoms are accompanied by a fear of death or impending doom, of becoming insane, or of losing control. The victim wants to rush home. Feelings of unreality, such as the sensation of being outside one's body, or of peculiar changes in the quality of light, may occur."

Nearly one in every 12 persons suffers from a mild to a moderate phobia, the psychiatrist said, and more than two per every 100 persons have a phobia that limits them in some way. The phenomenon generally runs in families.

Fear is an experience everyone has had at some point, and Agras says the seven most commonly reported fears are snakes, heights, storms, doctors, sickness, injury and death.

"Although a fear of a harmless snake may be intense , or may extend to a fear of crawling insects and mice,...such a fear is not likely to interfere much with everyday living."

In the last decade, Agras said, doctors have made tremendous advances in understanding and treating fears and phobias—that point at which fears begin limiting functioning.

While agoraphobia (fear of open spaces) strikes only 0.6 percent of the general population, it is the most common phobia doctors see at the Stanford University Clinic, Agras said, and it can keep someone housebound and severely limit their lives. About half of the some 150 phobic patients at Stanford each year are suffering from agoraphobia.

While this is an oversimplification, he said the cause might ultimately be traced to "the separation fear—the child's fear of separation from the mother, from venturing out into the world where they might be hurt."

6-3-85

-more-

He said agoraphobics should not be seen as weak. For many of these people, Agras said, it takes enormous courage just to leave the house to go to work each day. Some depend on their spouses or friends to take care of simple chores like supermarket shopping.

"Some of these people who have panic attacks think they are having heart attacks," Agras said. "They are not. I don't know of anyone who has ever died from a panic attack, but it can be terrifying nevertheless."

Doctors have achieved great success prescribing antidepressant medications, such as Imipramine, combined with the therapy of gradual exposure to the feared situations.

"If someone is afraid of snakes, we don't force them to go into a snakepit," Agras said. "We might begin by showing them pictures of snakes, then having them touch a stuffed snake, then taking them to the zoo where they can observe live snakes, and then perhaps holding a snake. With people suffering from agoraphobia, we encourage them to gradually take on some of the activities they've been afraid to do."

Within the last 20 years, doctors started changing the way they treat phobias, Agras said. They used to treat phobias with traditional psychotherapy—looking for whatever it was in the patient's background that created the fear. But, Agras said, psychiatrists have gotten extremely encouraging results with exposure therapy—actually changing behavior by gradually exposing the patient to the feared situation or object without necessarily understanding what caused it.

"Avoidance of a feared situation blocks the normal process of unlearning the fear response," Agras said, adding that exposure to the phobic situation reduces compulsive behavior, as well as the underlying fear.

Support and encouragement of others helps motivate patients "to reaffirm the daily decision to expose themselves to their feared situations," Agras stressed.

More than 85 percent of people with simple phobias can be cured after just a few visits, Agras said, and many don't require medication. The more extreme cases take longer, but generally the medications that help block panic attacks can be discontinued after about six months, he added.

"No matter what avoidance one has," Agras said, "it can and should be overcome."

ADVISORY

Editors, news directors: The following sent Business Wire Tuesday p.m.

STANFORD—

The news media are invited to a briefing and tour of Stanford University Medical Center's new $12 million Research Animal Facility at 10:30 a.m., Friday, Aug. 2.

The state-of-the-art facility recently opened and is the primary care area for the approximately 17 to 25 species of animals which typically are housed for research at the Medical Center. The facility replaces several scattered housing areas for animals. While most research is carried out at other locations, the Research Animal Facility contains several surgical suites and intensive care facilities for a variety of species and includes innovative environmental and health monitoring systems.

Animals have been moved into the facility gradually since about mid-June and most systems in the 32,000-square-foot complex now are fully functional.

Dr. Thomas Hamm, a veterinarian who heads the Division of Laboratory Animal Medicine, will lead the news media tour and answer questions. Photographers are welcome. Animals currently housed in the facility include cats, dogs, pigs and ducks. There may be an opportunity to observe an ongoing research project if one is in progress at the time of the news conference.

We hope to have available one or more scientists who use animals in research. Some areas of the building, including a biohazard area, are expected to be unavailable for entry.

To find the facility, arrive at the Medical Center along Campus Drive West. Turn into the Medical Center parking lot near Fairchild Auditorium by turning AWAY FROM the mountains and AWAY FROM the main part of campus onto Panama Street or Via Ortega.

Newsmen may park in the employee lot (marked for 'A' or 'C' stickers). Please display news media credentials on the driver's side of the front dashboard to avoid towaway or citation in the employee lot. The Research Animal Facility is located down outdoor stairways near Fairchild Auditorium.

A driveway leading to a loading dock also is available for temporary parking to offload gear.

HOUSING NEEDED FOR OUT-OF-TOWN PATIENTS

STANFORD—

The department of social services at Stanford University Hospital is seeking information from community members regarding possible free or inexpensive housing for out-of-town patients and their families.

The urgency of the housing situation warrants public concern, said Wil Wright, director of Stanford Hospital's department of clinical social services.

Long-term patients from outside the Bay Area, from around the nation and the world needing low-cost places to stay in the vicinity while being treated at Stanford Hospital include transplant candidates, oncology patients, medical and surgical patients.

"It's difficult to find affordable temporary housing in this area for any considerable length of time," said Wright. "If members of the community are made aware of the situation, perhaps they can help."

One family recently was placed by social workers at four different locations in five weeks—an example of the continuing problem in finding adequate temporary housing for patients.

A "Hometel," a joint project by Stanford University and the Assistance League of Santa Clara County, is hoped to alleviate some of the problem with 42 apartment units on Welch Road in Palo Alto. But its expected completion is mid-1987, as much as two years away.

The Assistance League has also provided several low-cost rentals to patients and their families at Oak Creek Apartments for the past few years. But the units have been 100 percent occupied with a long waiting list since the program began in 1978.

"The housing shortage is a problem we've always had and we always will have," said Duane Walker, associate director of Stanford Hospital. The current appeal, he explained, is part of the hospital's "ongoing response to our patients' needs and concerns."

What the hospital now seeks are people going out of town on holiday or otherwise vacating their homes for a short time, or people who have extra rooms they might make available free of charge or for no more than $7 to $10 per night.

Several community members have already begun the practice of sharing their homes with out-of-town patients, an arrangement that has brought benefits to both parties, Walker noted.

Also, a local hotel has recently offered to make discount prices available to Stanford Hospital patients and families on a limited basis, especially in emergencies.

Anyone willing to share or rent housing space is asked to call Pat Ochoa, patient assistant specialist, at (415) 497-5091, between 9 a.m. and 5 p.m. weekdays.

COMMUNITY PHYSICIANS SUPPORT HOSPITAL MODERNIZATION

STANFORD—

A $100,000 check from the Palo Alto Medical Clinic (PAMC) has has been received as a contribution to Stanford University Hospital's modernization plan, a physician leader announced Friday (July 26).

Dr. Alfred P. Spivack, a Palo Alto physician who heads the community physicians steering committee fundraising for the project, said the check brings to $1.7 million the amount either received, pledged or otherwise intended for the $114 million project from physicians or physician groups who use the hospital. Spivack said the physician goal for the project is $2 million out of a total fundraising goal of $15 million.

Approximately $80 million has been obtained through issuance of tax-exempt bonds, about $20 million is to come from hospital reserves, with the remaining from gifts.

On July 2, the Faculty Practice Program, which guides the patient treatment activities of the 280 full-time Stanford faculty doctors who use the hospital, announced a pledge to the project of $1 million over five years.

In addition to the group practice gifts, about 100 individual physicians have contributed or pledged $200,000 toward the project, scheduled for completion in the fall of 1987. These doctors include members of the full-time Stanford faculty, PAMC, Menlo Medical Clinic, as well as other physicians in private practice who use the hospital.

"Physicians recognize the need for better patient care and are making their own financial contibution to create the finest hospital possible," Spivack said.

Stanford University President Donald Kennedy, who also serves as chairman of the hospital board, said, "the burgeoning support for this project from community as well as full-time faculty physicians shows the modernization project to be a vital community resource that warrants support from everyone in this area."

Spivack said PAMC's gift represents "a significant commitment from a physician group which utilizes and enriches a community resource—our hospital. The clinic's gift sets an example that the rest of us in the community need to join, not just follow."

In a letter on behalf of some 100 partners of the PAMC (the health care division of the Palo Alto Medical Foundation), clinic executive director Dr. R. Hewlett Lee said, "It is hoped that this will be the first of five annual contributions that the Clinic will make to the project."

Lee said PAMC clinic is "in full-hearted support of the modernization project and the unanimous decision of our executive board to make this contribution was enormously heartening to me."

The project includes remodeling of portions of the present facilty while adding about 357,000-square-feet of new space, including 20 new operating rooms and modernized nursing units which will provide modern patient room accomodations.

"This is in truth 'our hospital,' as it is the hospital of all other community physicians," Lee said. "It is imperative that we work together to make it the best hospital it can be as it continues to serve all the patients and physicians in our area."

Lee said PAMC's relationship with Stanford Hospital began in the late 1950s, when clinic physicians were instrumental in helping the medical center relocate to Palo Alto from San Francisco by guaranteeing patients.

He said PAMC physicians used the hospital for virtually all their patients who required hospitalization. In support of the hospital's academic role, clinic doctors donate more than 5,000 hours a year teaching Stanford medical students, he said.

Community physicians on the medical staff—those doctors who do not work fulltime on the Stanford faculty—number more than 700, said Spivack, who is in private practice in Palo Alto. A large percentage of the community physicians, he said, hold part-time, non-paying teaching appointments on the faculty.

ONE-DAY PSORIASIS WORKSHOP OFFERED

STANFORD—

A one-day session of the Self-Help Workshop on Psoriasis, sponsored jointly by Stanford University's department of dermatology and the Psoriasis Research Institute, will be offered free of charge to patients and their families Saturday, Aug. 10.

The workshop will meet from 10 a.m. to 4 p.m. (with a lunch break at noon) at the Psoriasis Research Institute conference room, 600 Town and Country Village, Palo Alto.

Patients and their families will be presented with information regarding the cause and course of psoriasis, treatment, preventive measures, myths, and research, said workshop director Dr. Lexie Nall, senior research associate and epidemiologist.

The session will consist of mini-lectures with slide presentations, discussions with patients and health care professionals, and handout materials.

The free self-help workshop is ordinarily given in four two-hour weekly sessions, said Nall. "But some people can't commit to four sessions, so we decided to also give the one-day format a try."

Registration for the upcoming session, which can accommodate about 50 participants, may be made by calling (415) 497-7967. Registration forms are also available and may be returned to Nall at: Department of Dermatology, R156, Stanford University School of Medicine, Stanford, CA 94305.

7-25-85 —30— Lexie MC ReleasesLA9

Hultgren added that deaths and disabilities due to altitude sickness can be prevented and treated.

Sarnquist, a veteran climber who was a mountaineering guide in the Eastern Sierra Nevadas in the 1960s, said the 1981 American Medical Research Expedition to Everest confirmed that humans can adapt to the thin atmospheres of high altitudes.

On that expedition, Sherpa porters carried stationary exercise bicycles and medical laboratory equipment to above 20,000 feet. The team, which included scientists and professional climbers, were wired for electrocardiograms and carried equipment to measure their breathing capacity at the 29,028-foot summit. Numerous blood tests to study metabolism were performed, and other tests monitored brain functions and breathing during sleep.

Researchers found that climbers breathed more often or deeper than they'd expected, and so, were able to raise their oxygen level. Possibly because of the higher oxygen content, their blood was more alkaline and less acid than anticipated, and so the climbers were able to do more work and exercise at a higher altitude than expected.

Sarnquist also participated in a Soviet-sponsored mountaineering expedition in the U.S.S.R. in 1974. The nations represented included the United States, Russia, Holland, Italy, Germany, France, Great Britain, Scotland, and Japan.

Sarnquist survived "a couple of avalanches" on that trek, but two participants, one of them an American, were not so lucky and perished on the expedition, he said.

"Mountaineering is an incredibly intense experience," Sarnquist said. "It's an exercise in trust and physical stamina. You live with people for long periods of time under stressful conditions. The scenery is sometimes fabulously beautiful. And probably because of the intensity of the experience, food tastes better when you're hungry, water tastes better when you're thirsty. And you always end up learning a lot about yourself and your body."

Those wishing further information about the seminar in Equador should contact Hultgren at (415) 493-5000.

DIRECTOR OF FINANCIAL AID, STUDENT AFFAIRS NAMED

Photos available on request if not included.

STANFORD—

Earl Smith has been named director of the office of student affairs and director of the office of financial aid at Stanford University School of Medicine, announced Dr. John Steward, associate dean for student affairs.

Smith, whose appointment was effective July 1, has more than 20 years of experience in student financial aid administration at both public and private institutions.

For the past 11 years Smith served as associate director of financial aid at the University of Illinois Health Science Center in Chicago, one of the largest of such centers in the country. There, he designed and implemented a comprehensive computerized financial aid system serving more than 3,000 students.

Smith's experience at the University of Illinois also encompassed other areas of student affairs, including student orientation, commencement, and efforts to increase the number of health professionals from ethnic minorities.

At Stanford, Smith will direct the financial aid operation of the medical school, formulating policy to conform to state and federal regulations as well as to the needs of students and the institution, and working toward the continued smooth delivery of financial aid to students. He will also be involved with such activities as medical school orientation, student government and organizations, and management of the office of medical education.

Smith replaces Marcia Sexton in the office of student affairs. Sexton had relocated with her husband to the Laguna area last February.

Smith received his B.A. at Valparaiso University in Indiana, in 1961. He then pursued some graduate work at Northeastern Illinois University, Chicago.

On arriving at Stanford, Smith said, "I look forward to being able to serve a much smaller medical student body with a more personalized approach than was possible at the University of Illinois."

HEALTH HAZARDS OF MOUNTAIN CLIMBING

STANFORD—

Two mountain medicine experts on the faculty of Stanford University Medical School will be among those conducting a unique high altitude climbing seminar in Quito, Equador this December.

"The seminar is for physicians and other health professionals with an interest in mountain medicine," said Dr. Herb Hultgren. "It used to be that only hardy climbers had access to certain high mountain regions, but in the last few years, modern travel has made it possible for others to get there, and there are certain high altitude medical problems that health professionals should know as much about as possible."

Dr. Frank Sarnquist, who is an associate professor of anesthesiology (clinical) at Stanford and assistant chief of the anesthesiology service at the Veterans Administration Medical Center in Palo Alto, said the seminar curriculum will include discussions on high altitude pulmonary, cerebral, and systemic edema (excessive fluid in tissues), mountain sickness, cold injury, and traveler's diarrhea. The participants also will perform experiments on each other to illustrate physiologic changes due to high altitude exposure.

In 1981, Sarnquist climbed with the American Medical Research Expedition to Mt. Everest—the first team to perform medical experiments above 26,000 feet to determine the effects of extremely high altitudes on humans.

Hultgren, who is a staff cardiologist at the Palo Alto VA in addition to his Stanford affiliation, has spent years researching high altitude pulmonary edema, or swelling of the lungs. Symptoms include headache, nausea, vomiting, low blood pressure, and increased heart rate. The climber might act disoriented, cough and wheeze, perhaps even claim to hear a "bubbling" in the chest. He or she might not be able to sleep, complain of dizziness and cough up a whitish liquid.

Hultgren said people who experience those symptoms should be moved to a lower altitude as quickly as possible, and oxygen should be administered. The earlier the symptoms are recognized the better the chances for a successful treatment, he said. He added that pulmonary edema can affect anyone, including those in the best physical condition, if they climb so fast the body can't acclimate.

The conference in Equador will be held from Dec. 2 through Dec. 11. It is being sponsored by the Palisade School of Mountaineering in Bishop, in cooperation with Stanford. The schedule includes climbs to Cotopaxi's summit, above 19,000 ft.

Hultgren said he often is consulted by other physicians who ask if it's safe for their patients with heart or lung conditions to travel to high altitudes. "Each case has to be evaluated individually, but this seminar can help physicians make those decisions," he said.

CANCER BIOLOGY TRAINING APPROVED FOR FIVE MORE YEARS

STANFORD—

A one-of-a-kind training program in cancer biology for graduate and postdoctoral students has been approved by the faculty senate at Stanford University for another five years.

Presently supported by a $500,000 per year grant from the National Cancer Institute, the program is thought to be unique in the country, said Dr. Errol Friedberg, the program's director.

"Cancer biology is rapidly becoming a recognized area of specialized study in molecular biology," Friedberg said.

"This program gives students rigorous training in the basic sciences as well as an understanding of cancerous disease in patients," he explained.

The dual focus helps fill a growing need for trained research scientists with a knowledge of human disease, and also helps "bridge the communications gap that frequently prevents M.D.s and Ph.D.s from communicating," he added.

The program offers a Ph.D. in cancer biology to graduate students, and research training to postdoctoral scholars. Forty-two graduate students and nine postdoctoral fellows currently are enrolled. Approximately half of the Ph.D. students are working simultaneously toward an M.D. degree.

Students may choose as a preceptor any faculty member in the university whose research relates to the molecular or cellular regulation of normal and abnormal cell growth, Friedberg said. Thirty-seven faculty members in departments such as pathology, oncology, radiology, and biology currently supervise cancer biology students.

"The variety of research opportunities available to students is a great strength of the program," said Friedberg, a professor of pathology whose own lab this year houses three cancer biology students.

"We receive applications from some of the best students around the country who are planning careers in molecular biology," he added, "even though the program is relatively young."

Six students have earned Ph.D.s since the program began nine years ago, he noted, while another handful is near graduation, having completed all the necessary requirements.

The $2.5 million NCI grant that has supported the program for the past five years is up for renewal next year, Friedberg said.

The federal training grant funds 16 positions—four students for four years. Those not supported through the grant use a variety of alternative sources of funding, Friedberg said.

At Stanford, faculty senate review and approval is required every five years for interdepartmental Ph.D. programs, Friedberg explained. The faculty committee—chaired by cell biology professor Dr. Lubert Stryer—that reviewed the cancer biology program for the faculty senate, said in its report that the program is "thriving and is making a distinctive contribution to graduate education at Stanford."

At its June 13 meeting, the faculty senate unanimously approved the program's continuation, effective Sept. 1, 1985.

One unusual feature of the program is that every other year, in place of the core course requirement, senior students help organize a series of minicourses on cancer-related topics.

"It's quite an educational experience for them," said Gina Johnson, cancer biology program administrator. "They learn how much effort it takes to organize and teach a graduate level course."

INTERNATIONAL CONFERENCE ON ONE OF BIOTECHNOLOGY'S MOST PROMISING BACTERIA

EDITORS: An international conference on advances in the genetics and biotechnology of *Bacilli* will be held at Stanford University Medical School's Fairchild Auditorium July 15-17. Copies of the program may be obtained by calling the News Bureau. Members of the press who are interested in attending should also contact Dr. A.T. Ganesan at (415) 497-5806.

STANFORD—

One of biotechnology's most promising bacteria—*Bacillus subtilis*—will be the focus of a major international conference to be held next week (July 15-17) at Stanford University Medical Center.

Three hundred scientists from more than 17 countries, including the Soviet Union and the People's Republic of China, will assemble to discuss new prospects for genetically modifying *B. subtilis* and related *Bacilli* to produce a variety of valuable chemicals, ranging from insecticides to antibiotics to human hormones and useful enzymes.

The meeting, the Third International Conference on Genetics and Biotechnology of *Bacilli*, is sponsored by Stanford and by Syntro Corporation, a La Jolla biotechnology company that also sponsored a similar conference at Stanford in 1983.

The conference will be opened by two Stanford biochemistry professors who were pioneers of recombinant DNA techniques: Dale Kaiser and Nobel laureate Paul Berg.

Although *Escherichia coli* is the current genetic engineering industry workhorse, *Bacilli* have several advantages that may better adapt them as bacterial factories, explained Dr. A.T. Ganesan, who is a Stanford genetics professor and conference organizer, along with Dr. James Hoch of La Jolla's Scripps Clinic.

One attribute that makes *Bacilli* appealing to the biotechnology industry is their ability to secrete some of the proteins they manfacture.

"This secretion is genetically controlled," Ganesan explained. "We believe that it is possible to insert into the DNA a gene for a protein you want, coupled to the secretory mechanism. The bacteria should then secrete the product out into the growth medium, where it can be easily collected instead of breaking the cells open and then going through a complicated purification process."

Bacilli are soil bacteria that do not cause human illness, and therefore pose no health threat even when grown in the large quantitites required for industry, Ganesan added. In addition, unlike *E. coli*, they lack an assortment of chemicals that can be toxic to humans.

Another bonus of *Bacilli* is the diversity of potentially useful products naturally made by different strains. "Some *Bacilli* produce antibiotics; others produce specific insect toxins," Ganesan said. "There are so many different strains of *Bacilli* that nobody has even tested them for their potentialities."

One obstacle that has stalled bioengineers in harnessing *Bacilli* for commercial production is their ability to make and secrete enzymes that break down the biological products before they can be harvested.

But in the last year or two, scientists have overcome the problem by creating genetically engineered forms of the bacteria that lack the destructive enzymes. "These are already starting to become very useful," Ganesan noted, outlining some highlights expected at the conference, including reports on:

- *Bacilli* that produce large quantities of alpha-amylase, an enzyme that streamlines breakdown of starches into sugars (for example, corn starch in the production of corn syrup, a basic ingredient of many soft drinks and other sweetened foods);
- *Bacilli* that have been engineered to produce highly sought proteins such as interferon and human growth hormone—Finnish scientists have successfully introduced the human interferon gene into *B. subtilis* along with additional DNA sequences that cause secretion of the valuable protein;
- *Bacilli* that produce a toxin that is deadly to mosquitos—the toxin, which is undergoing tests in India, would be most useful in underdeveloped countries where malaria is endemic, as a possible safe and inexpensive replacement for poisons such as DDT;
- cloned genes from Bacilli for antibiotics such as bacitracin—new knowledge about genes from *Bacilli* that code for such antibiotics "will put us in a position to produce a new generation of genetically engineered antibiotics," Ganesan said.

There is a growing emphasis on *Bacilli* in industry, particularly in the agricultural, fermentation and biomedical sectors, Ganesan added. "Now that we know the chemical structure of useful proteins from *Bacilli* and the genes that produce them, in the future we will be able to design new sets of related proteins that we may want, and engineer new genes to produce them," he predicted.

DIABETES-NUTRITION STUDY SEEKS VOLUNTEERS

STANFORD—

Volunteers with diabetes are needed to participate in a study at the clinical research center (CRC) of Stanford University Hospital.

The long-term study seeks volunteers who have diabetes and are being treated with oral medications or by diet, but not with insulin injections. Researchers will continue their study of the effects of carbohydrate variations on the nutritional management of diabetes.

The study consists of two six-week periods during which volunteers will visit the CRC, with a one-week break between. The CRC will provide all meals. Participants will also receive a complete physical examination including laboratory evaluation.

Volunteers will receive a complete evaluation of their blood lipids, including cholesterol, triglyceride, and high-density lipoprotein (HDL) cholesterol information.

The study reflects "an increased awareness of the importance of nutrition in relation to health," said CRC director Dr. Gerald Reaven, professor of medicine. "This concern has been extended to the nutritional recommendations for individuals with diabetes."

Those interested in volunteering should call (415) 497-5430 between 9 a.m. and 4:30 p.m. for further information.

DIABETES-OBESITY STUDY SEEKS VOLUNTEERS

STANFORD—

Diabetic and non-diabetic volunteers are needed to participate in a study of the linkage of diabetes mellitus with moderate obesity and other abnormalities of fat metabolism.

Volunteers may be treated with oral medication or diet, but not with insulin injections.

The CRC study will include an oral glucose drink and glucose infusion to assess blood sugar, insulin, and fatty acid response. Also, researchers will study fat cell metabolism by performing a biopsy and removing two tablespoons of fat tissue from the abdomen.

The study requires approximately three-and-a-half days in the CRC at Stanford Hospital. These can be scheduled at the subject's convenience.

Participants will receive a complete physical examination and screening laboratory evaluation. In addition, they will have an opportunity to continue on a weight reduction program using a liquid formula diet. For those who participate in weight reduction, studies will be repeated after weight loss.

Interested volunteers may call (415) 497-5430 or (415) 497-6973 between 9 a.m. and 4:30 p.m. for further information.

NARCOLEPSY CONFERENCE SCHEDULED

STANFORD—

The Second International Symposium on Narcolepsy is being sponsored July 6-7 by the Sleep Disorders Center at Stanford University Medical Center.

Scientists from Stanford, other U.S. institutions, as well as researchers from several countries, including Japan, France, Czechoslavakia, and Belgium will discuss the latest efforts to understand the neurologic disorder which affects more than 250,000 Americans, said Dr. William C. Dement, professor of psychiatry and director of the Sleep Disorders Center.

Dement said that the focus of current research is to better understand the genetic base of the illness, which causes people to lose control over when they sleep. Narcoleptics tend to be sleepy during the day and may have sudden, uncontrolled sleep attacks while engaged in normal activities, he said.

Currently, medications can be prescribed to maintain wakefulness, he added.

Dogs, subject like humans to narcolepsy, have been instrumental in studies leading to a better understanding of the condition, Dement added.

The conference is being held in Fairchild Auditorium. For further information, contact Stuart Rawlings or Laurie LaBerge, (415) 497-8131.

The first international narcolepsy symposium was held in France in 1975.

DISMAL OUTLOOK FOR AIDS, STANFORD SCIENTISTS PREDICT

STANFORD—

The outlook for the spread of AIDS—Acquired Immune Deficiency Syndrome—is dismal and will get worse in the future, Stanford University Medical Center scientists predict.

Blood banks and society as a whole fail to realize how big the problem is and how much it will impact the health care delivery system, wrote Drs. Edgar Engleman and Jeff Lifson in the current issue of *Stanford Medicine*.

Engleman is associate professor of pathology and director of Stanford's blood bank. Lifson is a postdoctoral fellow in the pathology department. Both are involved with AIDS research.

"Nearly 10,000 cases of AIDS have been documented," they wrote. "Reported cases doubled in all risk groups in 1984 and are expected to double again in 1985. The true number is probably at least three times and possibly as many as ten times greater.

"In San Francisco two to four people are expected to die from AIDS every day next year," Engleman and Lifson said. This is in spite of improved screening methods of donor blood and increased awareness of AIDS.

The first 7,200 cases of AIDS, they wrote, have already consumed 1.3 million hospital days and have generated more than $1 billion in health care costs. Yet patients had a median survival of only 12 months.

Transmission of the disease via blood transfusions accounts for only a small number of AIDS victims. The actual risk to transfusion recipients, the authors wrote, is at most one in 100,000. With improved screening methods of donor blood, that number "should become vanishingly small in the future."

Engleman's and Lifson's article, "Special Report on AIDS" recapped Stanford blood bank's attempts to halt transmission of the disease through blood donations by screening patients who were at high-risk, soon after the disease surfaced. Because of their efforts, they said, they faced "negative and hostile" reactions from other blood banking institutions.

7-3-85 -more-

"Chief among the objections was the contention that screening was unnecessary because there was 'no proof' that AIDS was transmissible by blood transfusion," they wrote. Other blood banks assumed people who fell into high-risk groups would voluntarily refrain from donating blood, Engleman and Lifson added.

"To date, no cases of AIDS have been reported in Stanford Blood Center recipients who received screened blood," they observed. "Nearly 150 cases of transfusion-associated AIDS have been documented—many in the Bay Area within the last year."

Lifson and Engleman said they understood why other blood banks tried to deny that AIDS could be transmitted via blood transfusions, but called it a "counterproductive, head-in-the-sand approach to the problem.

"Organized blood banking in the United States is highly dependent on the good will of volunteer blood donors. Thus it is extremely conscious of its perceived public image," they wrote. By associating AIDS with blood donations, the authors stated, other blood banks feared a decrease in donors.

By the spring of 1983, Lifson and Engleman wrote in the article, they "were convinced that more had to be done by blood banks to protect transfusion recipients from AIDS." Until then, blood banks depended on voluntary deferral from donors who suspected they were in high-risk groups. So, the scientists developed and implemented a screening procedure using tailor-made monoclonal antibodies to detect an abnormal ratio in the white blood cell compostition characteristic of AIDS victims. They knew by using the test they would exclude some healthy donors as well, but considered the loss, estimated to be two percent of the donor pool, acceptable.

The often-fatal AIDS surfaced in 1981, afflicting homosexual men, intravenous drug abusers, hemophiliacs or recent Haitian immigrants to the United States. Researchers in the United States and France have since found that a virus called HTLV-3 seems to be the cause of the disease. A screening test for this virus has just recently been developed and is now being used by many blood banks. The test works by measuring the presence of antibodies to what is believed to be the AIDS virus.

Stanford's blood bank began using the HTLV-3 test routinely in May. The new HTLV-3 test is more specific and at least as sensitive as the test the blood bank had used previously, Engleman said.

TRUSTEES ANNOUNCE TWO MEDICAL FACULTY APPOINTMENTS

STANFORD—

Dr. Inder Perkash has been promoted from associate to full tenured professor of surgery, and Dr. Eric Glasgow named professor of anatomy in surgery (teaching) for a five-year term, at Stanford University School of Medicine effective September 1, 1985.

The Stanford University Board of Trustees approved the two medical school faculty appointments at its June 14, 1985, meeting.

Perkash is also the Paralyzed Veterans of America Professor of Spinal Cord Injury, and chief of the Palo Alto Veterans Administration Medical Center Spinal Cord Injury Service.

He is widely recognized for his investigation of neuromuscular disorders responsible for malfunction of the bladder after a spinal cord injury.

Educated in India, England and at Stanford, Perkash has been working with Stanford engineers at the VA's Rehabilitative Engineering and Development Center to modify and develop robotic arms and other devices to help the paralyzed and those with limited muscular control regain some independence.

Perkash has served since 1980, also, as an associate professor of clinical urology, by courtesy, at University of California, San Francisco. Before joining the Stanford faculty in 1973, he held positions at Baylor College of Medicine in Houston, and at the Postgraduate Medical Institute and Nehru Hospital, Chandigarh, India.

Glasgow received both his undergraduate education and his doctor of medicine degree at Queen's University, Belfast, Northern Ireland. His residency was at Route District Hospital, Northern Ireland, and he was a senior research fellow in renal diseases of children at the University of Birmingham and The Children's Hospital, Birmingham, England.

He has served on the faculties of several universities including Queen's University and the University of Western Australia.

Glasgow's most recent affiliation has been at Monash University, Clayton, Victoria, Australia, as acting professor and chairman of the department of anatomy, and as Monash University Representative in Melbourne, Victoria.

He was a visiting professor of anatomy at Stanford in 1979, 1981, and 1982. For the term of his upcoming appointment, he will serve on the Stanford faculty half-time.

Glasgow belongs to numerous societies, including the International Society of Nephrology, a field which has been the topic of much of his study.

STANFORD'S WEIGHT LOSS PROGRAMS FIT EVERY TASTE

STANFORD—

Confused by all the different weight loss programs offered by Stanford University Medical Center?

No wonder. There are several, each with a different approach, appeal, or geared for a different audience. And doctors may be just as baffled in trying to match program with patient.

But all the programs listed below incorporate exercise and healthy attitudes with diet to achieve weight loss for persons who need it and who feel motivated to make that change in their life.

• About to be introduced on the scene is the new "weight kit" of the Stanford Center for Research in Disease Prevention (SCRDP). Different because it is a study—and because it is offered only to the Stanford community through the Health Improvement Program (HIP)—the kit nevertheless joins the ranks of already established weight loss programs offered by a variety of Stanford professionals. They include the following.

• The department of dietetics at Stanford University Hospital combines behavior modification, nutritional expertise, physical exercise and positive attitudes to provide an eight-week-long "Enlightening Experience" for adults three times a year.

Led by registered dietitians, the course, which uses guest psychologists and other Stanford professionals, has a fee of $325, with a $50 refund at the end if the weight loss is attained. This also includes instructional materials and some food, an individual counseling session, and monthly follow-up weigh-ins after the program ends. The course is open to the public, with enrollment limited to 20 participants per session.

• For the second year, dietetics this fall will offer the Stanford Weight Management Program for Teens, a 12-week course led by registered dietitians. With adolescents, "we don't really put them on a diet, but work on developing good eating habits," said Kristine Birge, registered dietitian. The *Shapedown Workbook* is used.

Parents are invited to two of the 12 weekly, late afternoon sessions. The course is open to the public, at a fee of $165.

• A recorded message at (415) 497-5432 provides information about the dietetics department's programs. Individual nutritional counseling is available weekdays, at $45 for instruction, $10 for instructional materials, and $30 for each follow-up visit.

• Stanford's department of psychiatry and behavioral medicine offers a comprehensive, medically-oriented adult weight loss program open to the public, which for $255 includes one individual session plus nine group sessions with about 10 people per group. Physicians are available to group members as needed. (Call 415-497-5065.)

Using a largely behavioral approach, the group focuses on factors of general lifestyle, including eating behavior, nutritional behavior, physical activity, and attitudes. "We introduce people to better coping skills with which to solve problems, and we help them become their own best therapists," said Susan Raeburn, clinical psychologist.

She said a five-year follow-up study of the program conducted several years ago looked for predictors of long-term success. Of no surprise, she said, was the researchers' finding that people who continued the behaviors they had learned during the course had the most lasting success. "Also," she stressed, "the most successful ones were those who had reached out for therapy at some point."

While the program has thus far been directed toward treating mild to moderate obesity, the clinic plans a new group, under close medical supervision, for the very obese.

All these obesity programs are part of a larger eating disorders clinic within the psychiatry department, which also deals with anorexia nervosa, a disorder in which victims are obsessed with thinness to the point of starving themselves, and bulimia, the binge/purge syndrome. The clinic is available to such patients 18 and over, offering inpatient and outpatient psychotherapy, behavior modification, and nutritional guidance.

• Summer camps for teenagers and children who want to lose weight are offered by the Stanford Laboratory for the Study of Behavioral Medicine, also within the psychiatry department.

Called SHAPE, the four- and eight-week programs are intended to teach weight loss through a balanced program of non-competitive exercise and healthful foods, said Keith Saylor, SHAPE co-director. The eight-week program includes instruction by professional male and female models in how to change image and wardrobe to fit a new self-image, Saylor said.

Groups are divided into 7 to 11 and 12 to 17 age groups. Costs range from $350 to $800. The price includes appropriate meals and snacks, as well as parent seminars. Field trips to wilderness areas and a video aerobics tape are provided with the eight-week sessions.

Interesed persons should call (415) 497-5065.

• The eating disorders clinic at Children's Hospital at Stanford (CHAS) (415-327-4800) offers a unique interdisciplinary approach specifically designed to treat both underweight and overweight teenagers through a team effort by nutritionists, child psychiatrists, and adolescent medicine specialists. The clinic sees obese teens as well as patients with anorexia nervosa and/or bulimia.

-more-

• CHAS is now offering a Shapedown program for overweight teenagers, using a group approach which combines behavioral techniques, nutritional guidance, and physical exercise. The fee is $100.

• HIP currently offers two other weight loss programs—emphasizing exercise as well as diet—only to Stanford faculty and employees of both the university and hospital:

Weight Loss by Mail, in the process of being somewhat revised, uses an individualized approach to weight loss with a correspondence format. There is an introductory meeting and a $25 fee.

Advanced Nutrition, also for $25, is actually aimed at lowering cholesterol but often has weight loss as a side effect, said Fran Carl, program coordinator. This course uses a correspondence format and individualized approach as well, with an introductory meeting and two other optional meetings.

"We think we can save our people here at Stanford quite a bit of money by offering a work-site health promotion program," said Dr. John Farquhar, professor of medicine and director of the SCRDP associated with HIP.

He explained that for every person who comes to a group weight loss program, there are many more interested in losing weight. "Most people look in books or try a diet rather than joining a group," he said, "and there are even fewer people who would come for individual counseling." (The preventive medicine clinic run by Farquhar also offers weight control counseling on an individual and couples basis.)

"But I think all the weight loss programs offered by Stanford Medical Center professionals are good," Farquhar said.

An outside opinion

The key question to ask of any program is how much evaluation and long-term follow-up go into it, said Dr. Keith Taylor, professor of medicine. "A realist would probably say there's no one program that will be 100 percent effective in all people, or even in 50 percent," he added.

"Probably the most valuable weight loss programs anywhere are those which focus on healthy living styles generally, with eating habits as a part of that," said Taylor.

"Perhaps the reason behavior modification techniques don't appear to work as well *alone* is that the achievement isn't associated as much with an improvement in self-esteem as it would be in the context of an overall healthier living style."

As for the current programs available at Stanford, Taylor said he did not know that any had been fully evaluated enough to recommend to an obese patient for referral.

"Each group thinks it has a better answer," he said.

STANFORD PHYSICIANS FINANCIALLY BACK HOSPITAL MODERNIZATION

STANFORD—

Faculty physicians at Stanford Medical Center have pledged $1 million to support the Hospital Modernization Plan, Dean David Korn announced Tuesday (July 2).

The decision to commit the funds over a five-year period was reached Friday, June 28, by the governing committee of the Faculty Practice Program, representing the approximately 280 full-time faculty doctors who use the hospital.

"This support by the Faculty Practice Program is a benchmark in support for this project," said Donald Kennedy, president of Stanford University and chairman of the Board of Hospital Directors.

"The financial involvement of the FPP—as well as other physicians in our community—is a strong message to our patients from those who care for them," Kennedy added.

"This is our effort to guarantee that our hospital will continue to offer the ultimate in state-of-the-art care for our patients," said Donald Harrison, chairman of the FPP and head of the division of cardiology.

The HMP includes remodeling of portions of the present facility while adding about 357,000-square-feet of new space but no new patient beds. It is scheduled to be completed in the fall of 1987.

The expected cost of the HMP is $114 million. About $82 million has been obtained through issuance of tax-exempt bonds. An additional $20 million is to come from hospital reserves, with the remaining from gifts.

Sheldon S. King, SUH's director and executive vice president, said patient care fees are not expected to be increased to pay for any portion of the HMP. The hospital expects to keep its rate increases in line with the inflation rate, King said.

The FPP commitment is the third largest sum pledged by any group so far, said King. The 18-member Board of Hospital Directors has pledged more than $2 million, while a group of leading area corporations, under the chairmanship of Syntex president Dick Rogers, has nearly reached its $1.25 million target.

Overall, the hospital has reached more than a third of its $15 million fundraising goal for the HMP, said John Ford, director of medical center development.

In addition to the FPP group pledge, Korn noted that individual full-time faculty members have contributed more than $130,000 to a current fundraising effort at the Medical Center, including the HMP and the new Center for Molecular and Genetic Medicine.

The modernization will provide 20 new operating rooms and additional wings of patients beds. While no beds are being added to the current total of 663, the project will allow an increase in the average square foot per bed from 891 to 1,387, near the average for teaching hospitals in the country, Korn said.

Korn said an important goal of the project is to keep pace with the fundamental changes in medical practice since the present structure was planned in the late 1950s. For example, a variety of high technology equipment creates pressure for larger patient rooms.

"The HMP includes a variety of amenities intended to make the facility more pleasant and efficient for patients, ranging from more private rooms and better treatment suites, to such improvements as traffic patterns which allow for more efficient delivery of medicine and supplies.

"New facilities for coronary and intensive care, as well as a new pharmacy will be built. Clinical labs will be consolidated and the overall ambience will be dramatically improved," said Korn.

The FPP commitment was expected to be submitted to the university Board of Trustees for formal approval in September.

NEW HOSPITAL BOARD MEMBER NAMED

STANFORD—

Donald H. Seiler, 56, founder and managing partner of Seiler and Company, Redwood City, has been appointed to the Board of Directors at Stanford University Hospital by the general members at their recent meeting.

The 17-member board sets policy for the hospital. It is comprised of community, medical and lay leaders, as well as university faculty and administrators.

Seiler is co-chairman, along with his wife, Ruth, of the Friends of Cardiovascular Medicine at Stanford University Medical Center. He is active in community organizations, serving as director of the Jewish Community Federation and director and officer of the Jewish Home for the Aged in San Francisco. He has held leadership positions in other charitable organizations and business associations during the past 20 years.

Seiler received his MBA at University of California, Berkeley, in 1950. He founded his company, which is involved with real estate, venture capital and business operation ventures, in 1957.

PHYSICIAN ASSISTANTS PARTICIPATE IN COURSE ON AGING

STANFORD—

No matter what our religious or ethnic backgrounds or our educations, there is one thing we all have in common—AGING.

But what is successful aging? Many health professionals agree that successful aging combines three elements: survival (longevity), health (lack of disability), and life satisfaction (happiness).

Six physician assistant teachers from around the country recently came to Stanford University Medical School for a three-week course in the care of well and ill elders. The curriculum included classroom work, as well as visits to a number of senior citizen centers in the area.

The six plan to use the material to help implement geriatrics in the physician assistant teaching programs in their areas.

"There are so many myths about aging," said Marc Dicker, who teaches P.A.'s at Wichita State University, "and I think it's important for people to know that. For example, the majority of old people are not senile. They don't have defective memories, and they're not disoriented. Their senses might have declined a bit, but that doesn't mean that their thinking is impaired in any way. Also, most of the older people I've known can be pretty active."

The Stanford training program for P.A. teachers, directed by Virginia Fowkes and Gwen Yeo in the Medical School's Division of Family Medicine, is funded by the Health Resources and Services Administration. In conjunction with Foothill College, Stanford also has a program to train physician assistants and nurse practitioners.

"This is the first time the federal government has funded a faculty development program for teachers of physician assistants," said Yeo. "It's significant that the training is for those who will specialize in geriatrics. Geriatrics isn't experiencing a glut of physicians like some other specialties so there's a real need in this area for concerned, well-trained P.A.'s. We plan two more of these training sessions for P.A. teachers, one next January and February, and the other next June and July."

Once trained, physician assistants often work with medically-underserved populations. Under the supervision of a physician, the P.A.'s can perform physical exams, take medical histories, assess and manage common acute and chronic medical conditions, treat wounds, and provide health education and counseling.

The six teachers who completed the Stanford training in August agreed they were most impressed with the range of care available to senior citizens in Northern California, particularly the day health care centers for the elderly, which, they said, might be unique to this area. The day centers are different, they said, because they offer more than just crafts and skilled nursing supervision. Many have physical therapy programs, speech therapy, occupational therapy, and other intense care programs.

A residential facility they felt also was unique is On Lok in San Francisco's Chinatown because it was designed to serve a specific ethnic population. On Lok is a longterm care program for frail persons over 55 who wish to stay in their community but have health or other problems that prevent them from living independently. They

also visited Lytton Gardens, a Palo Alto residential facility for healthy elders that offers outpatient P.A. services. In addition, the six observed programs offering health screening in a senior center, home health care, day health care for the chronically ill, intermediate care, and skilled nursing care with rehabilitation services for short-term residential stays.

The physician assistant teachers agreed they were impressed with the activities offered.

"Many of the health care centers we visited have exercise classes for the older people, even if it's just gentle exercise," said Kathryn Kundert, who teaches at the Medex Program in Seattle.

Marc Dicker added that he chose the geriatric specialty because he learns so much from the older people he assists.

Patricia King, who teaches at Mercy College in Detroit and works with seniors in the Hospice of Southeastern, agreed. "It really makes me angry when older people are written off as useless or complainers when they might be going through some physiological changes of vision or hearing that makes it difficult for them to relate to all the things going on around them," she said. "But that doesn't mean they can't be useful or that they're not bright. Older people are a storehouse of all of our history, and I, for one, learn a lot about life just from talking to them."

Dean Minton, who teaches at the Bowman Gray School of Medicine in Winston-Salem, said the older people he's observed "may have a greater appreciation for life than many young people, and it makes me feel good to help make the quality of their life as good as possible."

Minton said he was impressed with the day health care centers he has observed in California, and would like to see some of the therapy programs introduced into the residential and skilled nursing care facility in the Winston-Salem area where he currently works clinically. He also plans to incorporate some of the written course material he gathered at Stanford into the P.A. program he teaches.

"The experts say by the year 2000, there will be more people over 65 than under 25," said Minton, who graduated from the Bowman Gray P.A. program in 1983 after retiring as an Air Force chaplain. "Medical care has improved tremendously. We've wiped out lots of diseases, but many people still have to change their attitudes about the value of older people. Many of them can be active. Many of them can be productive, if we let them. Let's listen to them, talk to them, learn from them."

Patricia McKelvey, assistant director of the University of Iowa Physician Assistants program, said many of the older people she's seen are more concerned about losing dignity and autonomy than about dying.

"Feeling a sense of purpose is very important to a sense of well being," added Stacy Terrell, who teaches P.A.'s at the University of Oklahoma. "Older people have so much to contribute, and many of them have so much wisdom. It's important that we continue to make them feel needed and necessary, and that we treat them with respect. After all, with luck, we'll all be old people one day."

NEW GENETIC TEST FOR DIAGNOSING LYMPHATIC CANCER

STANFORD—

Stanford University researchers have shown that mycosis fungoides, a form of lymphatic cancer, can be sensitively diagnosed with molecular genetic techniques.

By analyzing DNA in cells from a patient's lymph nodes, scientists can detect the cancer earlier and monitor the cancer's spread more accurately than with conventional methods, said a report in the August 29 issue of *The New England Journal of Medicine*.

By adding mycosis fungoides to the list of diseases that can be positively diagnosed by DNA analysis, the report helps prove the rapidly growing clinical usefulness of modern molecular techniques, said Dr. Jeffrey Sklar, assistant professor of pathology at Stanford University School of Medicine.

The authors of the Stanford report are Dr. Lawrence Weiss, assistant professor of pathology, oncology fellow Dr. Eddie Hu, dermatologist Dr. Gary Wood, research assistant Courtney Moulds, pathology fellow Dr. Michael Cleary, Dr. Roger Warnke, associate professor of pathology, and Sklar.

The Stanford report is accompanied by two reports from Massachusetts General Hospital and the National Cancer Institute describing the use of DNA analysis in diagnosing other forms of lymphatic cancer.

The method used by the researchers specifically detects cancerous growth of T cells, white blood cells that form one branch of the body's immune defenses.

Similar techniques developed several years ago by Sklar and Cleary have already been used for positive diagnosis of B cell lymphomas, cancers of another major class of immune system cell.

Mycosis fungoides is a relatively rare type of cancer that starts out in the skin, later spreading to the lymph nodes and other internal organs. Early on, the cancer can be difficult to distinguish from other forms of skin disease, Sklar explained. More advanced forms of the cancer, when lymph nodes become involved, are often difficult to distinguish from benign inflammations.

It is important to find early signs of spread because then whole-body chemotherapy should be given rather than restricting treatment to the skin, Sklar said.

"But even an expert pathologist who examines biopsied lymph nodes through the microscope can sometimes have difficulty distinguishing mycosis fungoides from a benign inflammation in those tissues," Sklar said.

In uncertain cases like these, Sklar explained, the new method could become a valuable and practical diagnostic tool.

The test is a clinical advance that owes its existence to recent progress in basic immunology, including discovery of T cell receptor genes by Dr. Mark Davis of Stanford and his colleagues, Sklar said.

8-28-85 -more-

The test also takes advantage of knowledge about how cancers arise. Several years ago, Sklar and his colleagues developed an unambiguous way of distinguishing cancerous growth from benign growth, relying on the fact that a cancer consists of a "clone" of genetically identical cells. Benign growths which can outwardly resemble cancer, are not composed of genetically identical cells. Therefore, analyzing the genetic material, DNA, can lead directly to a definitive diagnosis.

The Stanford researchers performed the genetic analysis successfully in B cell cancers. B cells lend themselves to this approach because each cell has a telltale "signature," a slightly different pattern of DNA in the genes that code for antibody molecules. Therefore, if a B cell becomes cancerous, giving rise to a clone of daughter cells, they will all have the same genetic signature.

In the last year-and-a-half, Mark Davis and other scientists discovered that each T cell also has a unique DNA signature in the genes that code for a protein called the T cell receptor. This finding enabled Sklar and his colleagues, and others, to adapt the same method for diagnosing T cell cancers.

Among the advantages of the new method are its sensitivity—a cancer can be diagnosed on very small tissue samples even if only one out of every 100 biopsied cells is malignant.

The researchers performed the test on 14 patients, all of whom had mycosis fungoides as confirmed by microscopic examination of skin biopsy tissue. For each patient, they found the cancer cells' telltale genetic pattern. They then looked at biopsy samples from lymph nodes that under the microscope appeared benign. In seven out of nine of these samples, they found the cancer cell signature using their new molecular test.

These findings suggest that spread of mycosis fungoides to the lymph nodes frequently cannot be detected with conventional methods, Sklar said.

The research was supported by grants from the National Institutes of Health and by fellowship funds from the Jane Coffin Childs Memorial Fund for Medical Research and the John A. Hartford Foundation.

STANFORD SCIENTISTS FIND UNUSUAL BURSTING CELLS IN THE BRAIN

STANFORD—

Unusual brain cells that fire in bursts which may trigger epilepsy have been identified by Stanford researchers.

The unique ability of these "bursting cells" to readily discharge a volley of electrical impulses makes them likely instigators of epileptic seizures, said Dr. Barry Connors, assistant professor of neurology at Stanford University School of Medicine.

Seizures result when large numbers of nerve cells in the brain suddenly synchronize their electrical activity. The abnormal rhythm produces the convulsive movements, fainting, or episodes of confusion that afflict the two million Americans who suffer from different forms of epilepsy.

Most people stricken with the disorder live normal lives with the help of drugs that prevent seizures by stopping the spread of aberrant electrical activity. But these medicines can cause side effects. And the seizures of 10 to 20 percent of epileptics are not fully controlled by currently available medications.

If proved conclusively that bursting cells indeed are the ones that start an attack, learning more about them could lead to design of drugs to stifle epileptic discharges at their source.

"We could target a drug towards them to shut them off specifically, rather than depress the whole central nervous system," said Connors. "This is the way anti-convulsants tend to work now."

His work is funded by the Division of Research Resources of the National Institutes of Health, other NIH grants, and the Klingenstein Foundation.

The bursting cells are a subset of pyramid-shaped nerve cells in the cortex, the outer shell of the brain that is especially prone to epilepsy.

Pyramidal cells in the cortex send out a network of spidery fibers that form an extensive web of connections with other nerve cells in the brain. They normally fire one pulse at a time when activated by other neurons.

But when bursting pyramidal cells are stimulated, they fire in staccato rounds of three to five pulses.

Previously, pyramidal neurons with this ability have been found, by other scientists, only in the hippocampus, a brain area also susceptible to seizures.

Connors speculates that in a normally functioning cortex, inhibitory neurons hold the excitable, bursting cells in check. But in epilepsy, deficiencies in the chemistry of inhibitory cells may allow trigger-happy bursting neurons to overwhelm the brain's normal balance between excitation and inhibition.

8-27-85

-more-

Besides suggesting new approaches to the rational design of new anti-epilepsy drugs, Connors said his research may lead to a better understanding of how the brain works.

If bursting neurons "have this ability to cause epileptic activity, to drive the other cells of the cortex so hard," he said, "that could be telling us about their normal function in processing information in the brain."

Connors used the specialized techniques of neurophysiology to locate the bursting cells within the cortex of rat and guinea pig brains.

With micro-electrodes and a precise manipulator, he pierced individual nerve cells within a thin slice of cortex, which he kept alive in a chamber that mimics the environment of a living animal's brain. The electrodes were needle-like glass tubes filled with a salt solution that conducts the electricity of nerve impulses.

The tips of the electrodes are so small, that several thousand of them could be accommodated by a pincushion the size of the period at the end of this sentence.

But since bursting cells are relatively small for pyramidal neurons, it took especially fine electrodes to find them.

"We had a run of very good electrodes recently," said David McCormick, a post-doctoral fellow in neurology who collaborated with Connors.

By injecting a fluorescent dye through the micro-electrodes after they had finished recording a neuron's electrical behavior, the scientists could find the cell under a microscope. They could thus correlate a cell's size and shape with its firing pattern.

And by localizing the bursting neurons to the middle layers of the cortex, Connors was able to explain his earlier studies, which had found that these layers are exquisitely responsive in experimentally-induced epilepsy.

Other researchers who collaborated in Connors' experiments are Dr. David Prince, chairman of neurology, and Michael Gutnick, who is now at DuPont in Wilmington, Delaware.

—30—

burstcon rf1

Spidery fibers of this pyramid-shaped nerve cell reach to contact other nerve cells. The cell, lit by an injection of Lucifer yellow dye, is one of the "bursting cells" that Dr. Barry Connors, assistant professor of neurology at Stanford University School of Medicine, has identified as possible triggers of epilepsy.

APPOINTMENT MADE BY DEAN KORN

STANFORD—

Dr. Michael Marmor has been appointed head of Stanford Medical School's division of ophthalmology in the department of surgery, announced Dean David Korn.

"I have two major goals," said Marmor, who has been acting head of the division for a year. "First is for the division to continue to provide the highest caliber of medical and surgical care possible, both primary and consultative. Second, I'd like to work toward establishing a stronger eye and vision research program, which will utilize Stanford's strengths in ophthalmology, and other academic resources. I'd like to facilitate, if not a collaboration, then an interchange with researchers in areas of neurobiology, molecular biology, and biomedical engineering."

The 44-year-old physician joined the faculty of Stanford in 1974 as assistant professor of surgery (ophthalmology). At the same time, he served as chief of the ophthalmology section of the Palo Alto Veterans Administration Medical Center, and continued to assume those responsibilities until 1984 when he became acting head of Stanford's ophthalmology division. Marmor continues to teach part-time at the VA.

He graduated cum laude from Harvard Medical School in 1966, served his internship at the UCLA Medical Center, and was a resident in ophthalmology at the Massachusetts Eye and Ear Infirmary.

In April of this year, Stanford's ophthalmology clinic established a new laser center for eye treatment. The three new lasers were purchased with a gift from the Televideo Foundation. One of those, a yellow Krypton laser, is one of only five in the world, Marmor said. The lasers are used to treat complications from diabetes, macular degeneration, retinal detachment, glaucoma, cataract corrections and other retinal vascular diseases, he added.

Before coming to Stanford, Marmor was an assistant professor of ophthalmology and director of the clinical electrophysiology unit at the University of California, San Francisco.

While at Stanford, he designed an inexpensive high-powered light to help people with night blindness get around in the dark. Unlike a conventional flashlight, the wide-angle mobility light casts a broad, intense beam that people with retinitis pigmentosa, severe glaucoma, or other diseases that impair night and side visions can easily follow.

In addition to his administrative duties, Marmor is an active clinician and surgeon. He was the first Stanford faculty member to do ultrasonic techniques of cataract extractions and intraocular lens implantations. As a researcher, Marmor is particularly interested in studying the physiology of retinal attachment and detachment and diseases of the retina, specifically aging disorders.

He also teaches an undergraduate course on how "the eye and vision can help someone develop an appreciation for art, literature and animal behavior."

Marmor is married to Dr. Jane Breeden Marmor, a radiation therapist at the Palo Alto Medical Clinic. The couple has two children, Andrea, 13, and David, 11.

Marmor enjoys playing the clarinet, listening to chamber music, and playing tennis.

DR. COX RETIRES AT AGE 78

STANFORD—

When Dr. Alvin Cox, Jr., retires from Stanford University Medical School on Aug. 31, he will end a family tradition that began in 1891.

Cox, 78, professor of pathology emeritus, joined the faculty in 1933. He was chairman of the Department of Pathology for 23 years, until 1964, when he joined the Dermatology Department to develop a dermatopathology laboratory and to do research in skin biology. Cox has continued to be active in research and teaching at Stanford.

His family has held Stanford faculty appointments since the opening of the University in 1891, continuously except for the years 1900-01, 1907-08, and 1910-15.

An uncle, Charles Cox, was an instructor and assistant professor of mathematics from 1891 to 1900. Cox's father, Alvin, Sr., was an instructor in chemistry from 1901 to 1907.

Cox, both of his parents, his two sisters, and his three children, are Stanford graduates. In addition, seven first cousins received degrees from Stanford University.

"I've seen Stanford change a lot through the years," Cox said. "When I came, the medical school was much smaller. We were in a rickety old building, and everybody knew everybody else."

During his career at Stanford, Cox has seen many technological advances in science, including the discovery of all the antibiotics and an extraordinary amount of knowledge about the chemistry of tissues.

He also is impressed with the advanced equipment. "Now we have microscopes where six people can look through the same microscope at the same time," said Cox. "And, of course, that's made a difference in teaching pathology."

Cox says the pre-War years were particularly significant for him. In 1935-36, he was an exchange assistant at the University of Freiburg, Germany.

On his way to Germany in 1935, Cox attended the XVth International Physiological Congress in Leningrad and Moscow. "It was the first time after the revolution that a group of foreigners was admitted to the Soviet Union," said Cox. "We were amazed at the grandeur of our reception. There were cocktail and dinner parties with caviar, eight or 10 kinds of wine, decorations of sculptured ice, tours of palaces and museums.

"That seemed very capitalistic to us, but it was obvious that the Soviets were doing serious work in science. Judging from the amount of American-made equipment there at that time, I'd say the Soviets were behind the Americans in a lot of areas. For example, we visited the Dnieper River dam in 1936, and were surprised to see that the generators were made by GE (General Electric)."

Once in Germany, Cox remembers quite "a bit of excitement" when Hitler moved his military forces into the Rheinland in the spring of 1936. Freiburg is about 15 miles from the French border, and there were days when he couldn't use his bicycle to cross the German-French border because of road barricades.

8-27-85

-more-

"Many people were frightened about what was going to happen as Hitler moved his troops," Cox said. "We all heard about Jews being persecuted, being forced out of good positions in science and other areas, and it distressed us a lot."

When he returned to Stanford in 1936, Cox began working with a pharmacologist from the U.S. Department of Agriculture, studying the chronic effects of toxic substances.

The pharmacologist, Floyd DeEds, did toxicity studies on substances proposed for use as insecticides, and Cox examined the treated animals. The two discovered that one insecticide the Department of Agriculture was ready to approve for use on crops, acetaminofluorene, caused tumors in rats.

"For some time, this was one of the relatively few known carcinogenic agents that was effective by mouth," said Cox, "and it was the one that produced the greatest number of different types of tumor. Of course, it was banned as an insecticide."

Another early research effort involved coccidioidomycosis (a fungus disease caused by infection), the progressive form of which, Dr. Cox said, "was thought to be a uniformly fatal disease at that time." Cox found four cases where the fungus was present, but it did not cause death.

In 1946, Cox met Mary Helen Files, who was working as a volunteer on social events for servicemen going overseas. Six months later, the two were married.

"I owe so much of my happiness to my wife," Cox says. "She, my three children, my three grandchildren and my work have helped make my life worthwhile."

In organizing a dermatopathology program in the mid-60s, Cox says, he used "many fine points of this superspecialty" he had learned during his sabbatical as a research fellow in 1957-58 at Harvard University.

In 1973, Cox was elected president of the American Society of Dermatopathologists.

Of particular interest to him has been the study of psoriasis.

"The trouble seems to be that surface skin cells grow too fast," said Cox. "In essence, that's what happens in cancer too, the cells grow too fast. But why the cells grow too fast in both of these diseases is still a mystery. Perhaps one day, in my lifetime, the answer will be discovered."

BRITTON TO TAKE LEAD AS NEW PRESIDENT OF MEDICAL STAFF

Photos available on request if not included.

STANFORD—

Dr. Melvin Britton, a rheumatologist at the Palo Alto Medical Clinic (PAMC), will become president of Stanford University Hospital's medical staff effective Sept. 1.

Britton, an associate clinical professor of medicine at Stanford Medical School, has been vice president of the medical staff for the past two years. As president he will succeed Dr. George Waltuch, clinical professor of medicine.

Britton is medical director of the PAMC's TakeCare health maintenance organization, through which he has spearheaded efforts to reduce patient hospitalization. "The trend in medicine must be away from using hospitals as convenience houses for doctors," he said in an interview. "In many cases hospitalization isn't necessary, or patients can receive medical work-ups in outpatient settings pre-admission."

The idea, he said, is not for doctors to treat patients differently depending on coverage, but to develop a "new appreciation of what can be done" most efficiently for all patients.

Britton said he hopes, as president, to represent all members of the medical staff, both faculty and community, especially on issues such as access, disciplinary matters, and insurance contracts where doctors may find themselves in conflict with hospital policies.

"Although there are a lot of influences that seem to set doctors against hospitals and cause competition, I think the answer to conflicts lies in cooperation between medical staff and hospitals," Britton said.

The main thing for all to remember, he said, is that "it's not the hospitals or the doctors we should be concerned about, but the patients."

Britton graduated from Harvard Medical School in 1960. He served his internship at the University of Colorado Medical Center, and his residency at Dartmouth Medical Center. He received fellowship training at the Robert B. Brigham and Peter B. Brigham Hospitals in Boston.

Between his internship and residency, Britton served in the U.S. Navy as a general medical officer assigned to Hawaii, from 1961-64. He has been in the U.S. Naval Reserve since 1964, currently as a commanding officer (rank captain) at the Navy Medical Reserve Unit at Moffett Field.

Besides his faculty appointment at Stanford, Britton is an attending physician in the school of medicine's division of immunology.

He has published widely. He is a member and has served on the boards of numerous professional groups.

At Stanford he has chaired the bed utilization review committee and the quality assurance committee, and served on the medical board and the operational advisory group for the Hospital Modernization Project.

At the PAMC, Britton is a member of the professional affairs committee and chairman of the quality assurance committee.

CETUS CORP. RESUMES GENETIC ENGINEERING LICENSE AGREEMENT WITH STANFORD

STANFORD—

Cetus Corporation has resumed a license agreement with Stanford University covering basic genetic engineering techniques, representatives from the two organizations announced Friday, Aug. 23.

Earlier this year, the biotechnology firm, located in Emeryville, Calif., had terminated the license agreement, which covers patented recombinant DNA technology widely used throughout the genetic engineering industry.

"We wanted to resume our license as an indication of the high regard we have for the close collaboration in many fields between our two organizations," said Robert A. Fildes, president of Cetus.

"Given the changes which have occurred over the last nine months in our business plans, the decision also fits in with our needs going forward," he added.

"Just as we were very disappointed with Cetus' decision to terminate their license earlier this year, we are delighted that they will resume the license," said Niels Reimers, director of Stanford's Office of Technology Licensing.

"In effect, the license will continue exactly as before, as if there had been no termination," he added.

The license agreement is based on two patents for gene cloning techniques, and certain recombinant molecules produced with those techniques, developed by genetics professor Stanley Cohen of Stanford and molecular biology professor Herbert Boyer of the University of California, San Francisco (UCSF).

The two patent applications were filed in 1974. The "process" patent issued in 1980 and the "products" patent issued in 1984.

Stanford administers the licensing program for the patents, and net royalties are shared between the universities.

Terms of the licensing agreement call for a sign-up royalty plus an annual $10,000 minimum royalty in addition to earned royalties on sales.

Companies that signed up before Dec. 15, 1981 received more favorable terms in applying sign-up and basic annual royalties as credit against future royalties on sales.

When Cetus terminated the agreement with Stanford, it forfeited the credits it had accumulated. However, in resuming the agreement with Cetus, Stanford agreed to reinstate the $250,000 in credits the company had earned.

This brings to 74 the number of companies that are licensed to use the patented technology. Over $3.5 million have been received since the licensing program was initiated in 1981.

HOSPITALS CHALLENGED TO DEFINE QUALITY, DOCTOR SAYS

STANFORD—

Consumerism in health care is challenging doctors and hospitals to define quality, says Stanford University Hospital chief of staff James Silverman.

"What we physicians call quality and what patients call quality are two different things," writes Dr. Silverman in the August issue of *Update*, the hospital's medical staff publication.

Silverman draws comparisons from the airlines. They have a similar problem in quality perception and doctors and hospitals might learn something from them.

"I would imagine a quality flight for the pilot is similar to a quality treatment by a physician," Silverman writes. "The bottom line for the pilot is the passengers' safe arrival. For the physician, it's the patient's recovery from illness.

"But consumers may find other aspects of their hospital experience more important, or at least, more measurable or understandable than flying an airplane or the performing of an operation."

Silverman compares common problem areas between airlines and hospitals to make his point:

Airlines

- Time waiting to board plane
- Crowded seating with little leg room
- Tasteless food
- Delayed departure
- Delayed arrival
- Waiting for luggage

Hospitals

- Time spent in admitting office
- Semi-private room with no privacy
- Tasteless food
- Delayed surgery
- Late discharge
- Waiting for discharge medicine

Silverman concludes that public perceptions of quality health care include the service portion—the amenities—as well as the treatment outcome.

8-22-85

-more-

"When very sick, the service portion has little meaning," he says."However, when recovered, patients remember all the frustrations that made their hospitalization uncomfortable."

Consumer perceptions create a serious dilemma, Silverman thinks, as funds are withdrawn from the health care system and institutions try to manage their costs.

"Should the funds be cut from the physician portion or the service portion? How can this be done sensibly, and is it possible?" he asks.

The answers are not so simple, Silverman responds. There are those outside medicine who think quality on the medical side could be improved and costs reduced by developing treatment protocols. Isn't there a best way to diagnose and treat pneumonia, anemia, or arthritis?

"We know," says Silverman, "that after 15 to 20 hospitals compared their coronary artery surgery data—taking years of study—it still is not entirely clear when or if to operate on large segments of patients with anginal pain." And not all doctors agree whether or not breast cancer should be treated with surgery or radiotherapy.

"Problems such as these make quality definitions difficult," comments Silverman. "We're going to have to continue to pursue choices between surgery and medicine, and we will have to force ourselves to find quality."

While physicians are making their efforts and letting the public know, the service part of the hospital must also press forward, he says.

"Hospitals have a long history of being difficult with patients," Silverman adds. "There seems to be tension through hospitals that often gets in the way and prevents their staffs from giving their whole attention to the patient.

"That must stop. Patients must feel all of a hospital's energy directed towards them—especially at the prices they are paying."

ADVANCE FOR RELEASE FRIDAY, AUGUST 23, 1985

TNF, AN EXPERIMENTAL ANTI-CANCER PROTEIN, MAY HAVE MULTIPLE ROLES

STANFORD—

The natural anti-cancer protein called "tumor necrosis factor" (TNF) may be identical to a substance that affects fat storage in the body, two groups of scientists have found.

The finding suggests new uses for the substance in treatment of chronic disease, as well as potential applications in controlling obesity, said a Stanford University Medical School scientist who heads one of the research teams.

The discovery also suggests that possible weight loss as a side effect could complicate the experimental agent's future role in anti-cancer therapy, said Dr. Gordon Ringold, associate professor of pharmacology at Stanford.

The discovery also raises new questions about TNF's natural function in the human body, where it is produced in small quantities by certain white blood cells, the scientist said.

TNF, which was discovered 10 years ago by researchers at Memorial Sloan-Kettering Cancer Center, has generated considerable excitement in the past year as biotechnology companies have begun to produce the purified substance in large quantities with gene splicing methods.

Its ability to kill a wide variety of cancer cells in tissue culture has pushed the protein to the brink of clinical trials in cancer patients in the U.S..

But in the August 30 issue of *Science* magazine, Stanford and Rockefeller University scientists describe how an unidentified substance, only in recent weeks shown to be indistinguishable from TNF, completely shuts down fat synthesis and storage in fat cells in the laboratory.

"This really opens up questions about what TNF does in the body," said Ringold, a biochemist whose main research interest is how hormones interact with the genetic material inside cells. "It may not be there to act primarily as a tumor-killing factor. TNF's physiological role may be to regulate fat metabolism or some as yet unidentified processes," he added.

Ringold's colleagues on the *Science* paper are Dr. Frank Torti, Stanford clinical associate professor of medicine and staff physician at the Palo Alto Veterans Administration Medical Center, Barbara Dieckmann, research assistant, and Drs. Anthony Cerami and Bruce Beutler, Rockefeller University biochemists. Dr. James Larrick of Cetus Corporation in Emeryville contributed to subsequent experiments confirming TNF's role, Ringold said.

The work was supported by grants from the National Institutes of Health, the March of Dimes, Rockefeller University, Cetus Corporation, the Veterans Administration, and the American Heart Association.

Recent experiments carried out in Ringold's laboratory show that TNF turns off genes that give fat cells their special ability to manufacture and store fat.

When fat synthesis and storage halts, it leads to a medical condition called cachexia, which is a wasting away of the body often seen in cancer patients and in people with chronic infections or parasitic diseases.

Ringold and his colleagues have shown that TNF's effects are similar to those of "cachectin," a protein that appears to be associated with cachexia. This is a potential side effect that will have to be carefully monitored in upcoming anti-cancer clinical trials, he noted.

The body's own TNF production may be the cause of cachexia in some cancer patients, Ringold added, and may even be the first diagnostic clue that something is wrong. Some people who develop cancer experience an unexplained loss of appetite and weight associated with cachexia before their tumor is even discovered, he said. Since laboratory studies have shown that only some tumors appear to be killed by TNF, this suggests that some patients might actually benefit by getting rid of their own internal TNF.

"It might seem contradictory to eliminate a natural body substance that has some cancer killing abilities from a cancer patient," Ringold observed. "But obviously in those cases where the cancer is already growing in TNF's presence, the protein isn't working very effectively against the cancer," he said.

In order to eliminate natural TNF from the body, an inhibitory drug would have to be found, Ringold noted. One possibility would be a monoclonal antibody that selectively neutralizes TNF. Such substances should be available soon, Ringold said. If developed, it could also be useful in patients who develop cachexia as a result of a chronic disease such as parasitic infections or tuberculosis, he added.

Ringold also suggested that administering TNF in a controlled fashion might be useful for treating certain forms of obesity. Although there is as yet no experimental evidence to support this, some biotechnology companies that produce TNF are interested in pursuing this research, he noted.

Cachectin was originally discovered in 1982 by Cerami and his colleagues, who gave the name to a "soup" of proteins from macrophages, white blood cells known to produce interferon, interleukin, TNF, and other proteins. When applied to fat cells in the laboratory, the protein soup shut down their activity, providing a lab model of cachexia.

In collaboration with Cerami and Beutler, Ringold and colleagues determined that the substance's ability to switch active, specialized fat cells into quiet nondescript cells, was exerted at the genetic level, by turning off specific genes.

The Stanford and Rockefeller groups then independently discovered the relationship between cachectin and TNF.

The Stanford group tested pure samples of the individual proteins thought to make up cachectin, to see if any one protein alone could cause the cachexic effect. Cetus' Larrick suggested trying their TNF, which turned out to be the cachexia-generating protein, Ringold noted.

At the same time, the Rockefeller scientists found a strong similarity between portions of the structures of mouse cachectin and human TNF, Ringold said. This work has just been published in the August 8 issue of the scientific journal *Nature*, he added.

SUH RATE INCREASES LOWEST IN 12 YEARS, DIRECTOR SAYS

STANFORD—

Stanford University Hospital will implement an overall rate increase averaging 7.9 percent, the smallest rise in 12 years, announced Sheldon S. King, executive vice president and director.

The new prices approved Wednesday (Aug. 14) by the Board of Hospital Directors take effect Sept. 1, the start of the 1985-86 fiscal year.

Price levels, which include daily rooming costs as well as all medical and related services, are based on a budget of $196 million. The budget—but not rate increases—must be submitted for approval to the university Board of Trustees, meeting as general members of the hospital on Sept. 10.

The budget proposes $6.1 million in capital improvements, including $401,000 budgeted this year for construction of a new linear accelerator for cancer treatment.

King noted that the $114 million hospital modernization program (HMP), scheduled for completion in 1987, "will bring far-reaching benefits to the community needed to bring the hospital into the 21st century." The HMP is funded from a variety of sources, including $82 million in tax-exempt bonds.

One of the most important components of patient charges is the daily care rate, which varies depending on the amount of nursing care required. The most commonly charged rate for a semi-private room with the benefits of round-the-clock housestaff (intern and resident) coverage will increase from $384 to $414. The rate without housestaff service will be $388.

Rates for another common category, obstetric patients, will be $389 with housestaff services, $363 without.

King said a cost management program enabled the hospital to cut $8.1 million in expenses this year. Much of the decrease, King said, was brought about by changes in the purchasing of supplies and services, including volume buying in conjunction with the university.

Following a trend of recent years, patients admitted are expected to have shorter hospital stays than in the past. In the fiscal year ending September 1984, patients were staying an average of 6.8 days. By Sept. 1, the average is expected to be 6.5 days, King said.

"Modern medicine as applied here at Stanford has enabled us to improve care and results while allowing the patient to return home sooner," King said.

FOR IMMEDIATE RELEASE

PROGRESS CONTINUES TOWARD URINARY TRACT INFECTION VACCINE

STANFORD—

A new finding, bolstering hopes that a vaccine can be developed to prevent complications of urinary tract infections, has been reported by Stanford University researchers.

The new finding shows that strains of *Escherichia coli* bacteria that cause severe urinary tract infections all possess certain genetic similarities.

This common genetic endowment is enabling the Stanford researchers to develop a vaccine that can target all the strains of *E. coli* bacteria that cause infection in the bladder or the kidneys, the scientists said.

Although a vaccine is not yet available for humans, the Stanford researchers have already tested in mice a prototype vaccine which was able to prevent urinary tract infections from spreading to the kidneys.

The new finding, published in the August 15 issue of *The New England Journal of Medicine*, "strengthens the evidence that we can develop a human vaccine," said Dr. Peter O'Hanley, one of the researchers, and an assistant professor of medicine and medical microbiology at Stanford University School of Medicine.

The work was conducted in the laboratories of Drs. Gary Schoolnik and Stanley Falkow. Schoolnik is assistant professor of medicine and medical microbiology and chief of infectious diseases at the Palo Alto Veterans Administration Medical Center. Falkow is professor and chairman of medical microbiology.

Other collaborators include Dr. David Low, now at the University of Utah, Irevis Romero, Dr. David Lark, and Dr. Kenneth Vosti, professor of medicine.

Urinary tract infections are among the most common medical problems of female outpatients, estimated to afflict at least 15 percent of women once in a lifetime, according to Schoolnik. Although usually not serious, the infections can be a major cause of discomfort and loss of work time, and can cost up to $150 to treat, O'Hanley said.

When a urinary tract infection is confined to the bladder it is called cystitis. In a small percentage of women with cystitis, the kidneys also become infected, causing pyelonephritis, a condition that may require hospitalized treatment and can lead to blood infections, and even to kidney failure in some cases.

Antibiotics are an effective treatment. But a vaccine to prevent infection would probably be more cost-effective, would spare considerable illness, and would minimize the use of antibiotics, to which growing numbers of bacteria are becoming resistant, Schoolnik said.

-more-

The majority of urinary tract infections are caused by *E. coli*, which are normally harmless bacteria that live in the bowels, O'Hanley explained. The new finding shows that only a few strains of *E. coli* are associated with causing urinary tract infection. These strains all possess similar genes that control production of certain proteins. These specific proteins enable the bacteria to cause infection and to invade the patient's kidneys, O'Hanley explained.

He and his colleagues at Stanford are designing vaccines that induce the immune system to produce antibodies that inactivate these proteins. Finding that all the harmful strains of *E. coli* use similar proteins to do their dirty work streamlines the task of vaccine design and strengthens the possibility that a vaccine against one strain would be effective against all the others, O'Hanley said.

The researchers analyzed bacteria from the urine of women with pyelonephritis and cystitis. They compared these with samples from women with high levels of bacteria in their urine, and with bacteria from the stool of disease-free women.

They found that 100 percent of the *E. coli* bacteria from women with pyelonephritis produced a protein that alllows them to latch onto tissues lining the bladder and kidney. In non-diseased women, only about 30 percent of the bacteria from the stool produced this protein.

They also found that 75 percent of bacteria from women with kidney infections produced a protein called hemolysin that helps break down cells lining the kidney. This protein was produced by only 14 percent of bacteria from the stool of healthy women.

"These proteins might form the basis for a broadly cross-reactive vaccine for the prevention of pyelonephritis," O'Hanley said. But he added that there are still many steps to be taken before a vaccine is proven effective and made available, including tests to make sure that the agent is safe for humans.

The research was supported by grants from the Cetus Corporation of Berkeley, the National Institutes of Health, the John A. Hartford Foundation, and the American Urological Association.

STANFORD ANESTHESIOLOGISTS MAKE HOUSECALLS AT SAN FRANCISCO ZOO

STANFORD—

A couple of Stanford anesthesiologists are wild about their work.

In fact, they're so enthusiastic they're even willing to arrange their schedules so they can make housecalls to their patients who live at the San Francisco Zoo.

When two snow leopards needed dental surgery, for example, they delivered the anesthesia while the dental surgeons operated.

And when a polar bear needed a CT scan, not only did they put him out but they had to carry him down two flights of stairs to boot.

They've put a lion to sleep while he underwent a vasectomy. They've anesthetized gorillas so the veterinarian could draw blood to be tested for virility, arthritis and growth problems.

While some of these procedures are relatively minor and take no more than a few minutes to perform on people, say Drs. Fred Mihm and Jim Scott, it's a completely different tale to tell when dealing with animals.

You just can't explain to a gorilla that you only need a couple of vials of blood and that drawing it won't hurt, they explain. Nor can you caution a polar bear to stay perfectly still so a CT scan will come out well. The only way to perform these procedures is to make the animals temporarily lose consciousness.

Veterinarians can do so for a minute or two by shooting a dart containing a small dose of anesthetic into an animal's body. But putting animals or people to sleep for longer time periods may trigger breathing or heart problems as well as other complications. The people most skilled to detect potential crises, monitor patients to make sure they don't occur and quickly react if they do, they say, are anesthesiologists.

"We're bringing hi-tech medicine to animals," says Mihm, an assistant professor of anesthesiology who has been volunteering his services to the zoo since 1983. "Zoos can't afford to lose their animals because of their cost, rarity or because they are gifts from other countries' governments. With our help, veterinarians can give the animals much more sophisticated medical care."

Speeding north on the freeway from Stanford University Medical Center towards San Francisco's zoo, Mihm describes today's case. Veterinarian Craig Machado needs some blood from Rita, an orangutan whom he estimates is about 20 years old. In addition to the standard tests, he needs to send some of her blood to be specially analyzed to determine which of two possible species she belongs to. Both are on the endangered list. The veterinarian called the anesthesiologists, Mihm explains, because of possible respiratory problems.

Driving out to Rita's cage in a motorized zoo cart, Machado explains the potential complications in more detail. Orangutans have a lot of tissue surrounding their neck, he says, and relatively small, collapsible airpipes. When she's out, he continues, they have to make sure the weight of tissue doesn't compress the airpipe and block it.

While Mihm, Scott, and anesthesiology resident Jim Pearson unload their portable monitoring equipment, about $25,000 worth donated to Mihm by private companies for this specific use, Machado checks on Rita. "She's known something is up since we isolated her this morning," he says.

Sure enough, Rita, hanging by her hands off the side of the cage, watches every movement as Mihm prepares the air gun with the dart containing the anesthetic. "It has to be a sure shot," Machado warns. If the full dose doesn't go in, they run the risk of overdosing her to compensate, which could endanger Rita, or underdosing her and endangering themselves by attempting to work on a still-active animal.

A momentary silence prevails as Mihm aims and fires. "Great shot," Machado exclaims while Rita looks a bit bewildered and then curious as she reaches out with her long arm and picks up the now-empty cartridge to examine it more closely.

In the following minutes Pearson begins to record all the data on Rita, while her head begins to droop and eyelids begin to blink.

"There are hardly any data at all on anesthetizing animals and their reactions to it," Mihm explains. "Having us come help is mutually beneficial. Data like ours will help veterinarians learn about anesthesiology, while we get to learn more about animals.

"We're used to intense situations like these because of the work we do with people," he continues. "The techniques we use are the same, although we sometimes do even more monitoring on the animals just because we're less familiar with how they're going to react."

Rita's head takes one final droop, and suddenly a flurry of activity erupts. Machado, Scott and Mihm leap into the cage, administer more anesthetic and start drawing a total of about a half a cup of blood. They carry the limp Rita out of the cage, quickly weigh her in at 146 lbs. and position her laying on her stomach back in the cage. Just as they begin to relax, Mihm starts. "No air is coming out," he says, holding his hand close to her mouth and nose. "Get me some tubes."

Mihm tries to insert tubes varying in diameter into Rita's trachea without success. As he discards one after another, he and Machado begin to sweat. "These tubes are too short," he observes. "Her airpipe is much smaller and much further back in her throat than a human's."

Giving up on the tubes, Mihm manually holds open her airpipe with a small tool. "Her trachea is as small as a four-year-old and much less rigid," he comments. The team watches Rita's heart beat on the monitors and the rise and fall of her stomach area. About 30 minutes later, her breathing has returned to normal. As her hands begin to flinch, a sign of regaining consciousness, they begin to withdraw their equipment.

"These animals are beautiful and they're smart," Mihm comments on the drive back to Stanford. "By working with them we're able to get much closer to them than we ever would in any other situation. People may think we're only interested in doing research on animals. But by administering anesthesia, we're offering a needed service and providing that extra margin of safety that the animals need."

WEIGHT MANAGEMENT COURSE OFFERED TO TEENS

STANFORD—

A 12-week course on weight management for teenagers has been scheduled for this fall by the Stanford University Hospital department of dietetics, announced clinical nutritionist Kristine Birge.

Combining diet, exercise and behavioral techniques, the "Shapedown Program" is intended to help teenagers take charge of their own weight management.

Classes for participants are scheduled from 4 to 5:30 p.m., Sept. 12 through Dec. 5. Parent sessions have been scheduled at 7:30 p.m., Oct. 3 and Nov. 7.

Cost for the program and materials is $165. The registration deadline is Aug. 23. For more information call (415) 497-5432.

WEIGHT MANAGEMENT COURSE OFFERED TO ADULTS

STANFORD—

An eight-week course for adults on weight management will be offered again this fall by the Stanford University Hospital department of dietetics.

"An Enlightening Experience," led by registered dietitians, includes a personalized weight loss plan, low calorie cooking demonstrations and recipes, menu planning and tips on dining out wisely, said dietitian Kristine Birge. Guest speakers in the program will discuss stress reduction, behavior modification techniques and exercise, she said.

Participants may register for either afternoon or evening sessions to be held in the hospital's north cafeteria dining room. The first evening class will meet 7:30 to 10 p.m., Tuesdays, Sept. 24 through Nov. 12. The first afternoon class will meet 1 to 3:30 p.m., Thursdays, Sept. 26 through Nov. 14.

Enrollment for each class is limited to 20 participants. The fee is $325 with a $50 refund if the individual's weight loss goal is achieved. Registration deadline is Sept. 10.

For further information, call (415) 497-5432.

VOLUNTEERS NEEDED FOR DIABETES DRUG STUDY

STANFORD—

Volunteers with adult onset diabetes are needed to participate in a study beginning at Stanford University Hospital's clinical research center (CRC).

Researchers under the direction of Dr. Gerald Reaven, professor of medicine, seek diabetics being treated with insulin who in spite of treatment are not under optimal control (whose fasting blood sugar levels are too high).

The study will attempt to gain better control by adding the recently released medication glipizide to their treatment.

Participants must be in generally good health and between the ages of 40 and 70. They will receive a physical examination, complete blood count, evaluation of liver and kidney function and cholesterol level, and an electrocardiogram.

After an initial brief hospitalization, participants will visit the CRC weekly for a period of four to six months.

Those interested should call Dr. Elizabeth Fraze at (415) 497-6973.

RESEARCHER FINDS EVIDENCE THAT HYPNOSIS CHANGES BRAIN ACTIVITY

STANFORD—

Hypnosis causes a specific change in the electrical activity of the brain, reports a Stanford University Medical Center psychiatrist.

Dr. David Spiegel, associate professor of psychiatry and behavioral sciences, said his research shows "a believable difference" in brain waves of hypnotized and normally conscious people. And, he said, his study provides a neurological test which distinguishes between people with high and low hypnotizability.

Under hypnosis, the brain's response to a pattern of colors was decreased, he reported in the August issue of the *Journal of Abnormal Psychology*.

People who are hypnotized can tune out what is actually coming to their eyes, and instead focus on an internally-generated image, Spiegel explained.

He said his findings are "a step towards understanding how people manage access to consciousness, how they control their response to pain or to unwanted ideas, the mechanism of mind over matter."

In his experiments, volunteers, who were Stanford students, watched colored patterns that were flashed on a television screen. Such visual displays evoke a characteristic change in brain waves, which Spiegel measured with an electroencephalogram (EEG).

An EEG records the peaks and troughs of electrical activity in the brain. And hypnosis altered a particular peak in the brain waves, Spiegel found. This peak was smaller in hypnotized subjects who were told to visualize a cardboard box that blocked their view of the colors on the screen.

The box was imaginary, but while in a hypnotic trance, students who were highly hypnotizable believed it was there.

No change in the peak was found in students who were not hypnotizable. They tried to visualize the blocking cardboard box but reported they could still see the screen, Spiegel said.

"When hypnotized people don't see what is actually there at all, they are dampening the way their brain responds to the stimulus," he said. "The process is something like turning down the volume on a stereo amplifier."

The peak suppressed by the hypnotically imagined box is usually activated when a person pays attention to an object such as the color pattern on the screen, Spiegel said.

He found that the peak was most suppressed in the back region of the brain, which interprets vision, and was especially dampened on the right side of that area. Scientists link the brain's right side or hemisphere with spatial and intuitive thinking, and the left with verbal and logical thinking. Other researchers have shown that people under hypnosis tend to rely more on their right brain hemisphere, Spiegel said.

He said hypnosis is a state of intense, focused concentration, in which mental perception is altered.

"It's really a form of alert concentration," Spiegel said. "It isn't sleeping."

Therapists today use hypnosis to help people concentrate on breaking habits, such as smoking, to conquer phobias such as fear of flying, and to control pain.

Spiegel will present his work Thursday, August 15 at a Toronto meeting of the International Society of Hypnosis and Psychosomatic Medicine, and then in New Zealand, where he will be the keynote speaker at the Annual Congress of the Australia-New Zealand Society of Hypnosis on August 24.

Spiegel's co-workers are Steven Cutcomb, Ph.D and Chuan Ren, M.D., both former students at Stanford; and Karl Pribram, Stanford professor of psychiatry.

STANFORD'S NEW ANIMAL CARE AND RESEARCH FACILITY OPENS

STANFORD—

Animals—and the humans who care for them—have begun moving into Stanford Medical Center's $11 million Research Animal Facility, said Thomas Hamm, veterinarian and director of the center's Division of Laboratory Animal Medicine.

The facility was approved by the university Board of Trustees nearly three years ago to augment the quality of biomedical research and care of animals.

Animals, ranging from ducks to pigs to dogs have moved in with the staff of more than 30 persons, including Hamm and two other veterinarians, as well as animal care technicians and office personnel.

"Stanford now has a state-of-the-art laboratory animal facility we can all be proud of," said Hamm. "The building's features will enable us to achieve the highest standards of research more easily while ensuring that our animals will receive the best care attainable from our staff of professionals and technicians.

"Fortunately, most of what is good for research is also good for the well-being of the animals," said Hamm. "You can't accomplish careful, competent research on highly stressed animals."

Among the features incorporated into the 32,000-total-square-feet structure is a filtration system that changes the air in the building up to 27 times an hour, which exceeds National Institutes of Health guidelines for animal care of 10 to 15 hourly air changes. Ventilation shafts extending 40 feet into the air mark the site and facilitate the air changes.

Air temperature can be precisely controlled, room-by-room to ensure that the thermometer conforms to an individual species' needs.

"Again, it's a question that an animal exposed to the proper temperature is going to be healthier than an animal facing conditions which are either too hot or too cold," Hamm said.

Water will be filtered to ensure purity—for the health of the animal, as well as to ensure that a foreign substance won't confound the results of experiments.

Sensor devices link with a central monitor which issue a warning to personnel when water or air standards deviate from normal. Steam cleaning equipment to sterilize cages and containers used in animal care is located in the building.

The RAF building is located underground with tunnels connecting to other research and instructional areas of the Medical Center.

"The location enhances our ability to control the environment for light and temperature, as well as permitting efficient access to the majority of our researchers," Hamm said.

While most of the actual research will be conducted in laboratories outside the building, the new RAF facility includes two operating rooms and an intensive care facility.

8-2-85

-more-

"We're one of the few animal care facilities in the country where professional personnel, including nursing staff on the premises and an on-call veterinarian, are available round-the-clock for the care of animals," said Hamm.

Even though the building has just recently opened, its presence has already led to perceived benefits. A research team led by Dr. Gerald Reaven, was told it would qualify for federal funding only if the proposed rat colony was housed in the new facility. An unusually clean atmosphere free of disease was needed for a study on aging.

"They needed a situation where rats would be able to live to a ripe old age (about 2 years) so that they could then study the endocrine changes that occur as the animals get old. We were told by the National Institute of Aging that the new facility would have to be used to provide state-of-the-art care that would help ensure long-term, disease-free survival," Hamm said.

The facility has been designed to house a continuously varied array of animals. Initial occupants which moved into the facility since mid-July included about 21 cats, five chickens, 13 dogs, 18 ducks, 15 geese, 70 guinea pigs, two mice, one pig, 301 rabbits, and 13 rats.

About 95 percent of the 45,000 animals at Stanford are rodents. Approximately 50 percent of the animals will be housed in the new facility, and Hamm said most are expected to be moved in by the middle of August.

But several larger animals, including sheep helping to develop a partial artificial heart called a left ventricular assist device, and some primates and dogs involved in a variety of transplantation and other cardiac studies, will remain in specially designed animal facilities in the 1-year-old Cardiovascular Research Building.

A campus kennel will continue to be used to quarantine many larger animals prior to research. Large rodent colonies, some numbering 15,000 or more individual animals, will continue to be located in various departments until a second research animal facility is completed in several years. That project is under active planning consideration and would be built partially in conjunction with the Center for Molecular and Genetic Medicine, a previously announced basic research endeavor expected to be open in its own building in 1988.

The trustees approved the new animal facility in December 1982 for a cost of between $10 million and $12 million. It was designed by the San Francisco architectural firm of Stone, Marraccini and Patterson. General contractor was Rudolph and Sletten of Foster City.

S. Corbin Smith, a university project manager, said the total project cost, including design, planning and financing was $11 million with actual construction costs of $7.3 million.

The project was funded with $3 million of University and Medical School reserves. The balance of the cost was provided by tax-exempt bonds through the California Educational Facilities Authority (CEFA), said David Mendelow, associate dean for administration.

LAB DIRECTOR COMBINES ANIMAL CARE WITH RESEARCH

STANFORD—

Dr. Thomas Hamm thinks Stanford's new $11 million Research Animal Facility will one day be the best place in the world for animals and research—including his own.

"I'd say in two more years, we might have the best animal program there is anywhere," said Hamm, director of the Division of Laboratory Animal Medicine at Stanford. "When I came to Stanford a year ago, this new facility was already under construction and there were plans to replace the outdated equipment. Right now, I'm recruiting a veterinary pathologist. A lot of other academic institutions in California have expressed an interest in using the Stanford lab once the pathologist is here."

Hamm, 42, came to Stanford from North Carolina, where he headed the department of general and biochemical toxicology at the Chemical Industry Institute of Toxicology in Research Triangle Park. The veterinarian also has a PhD in comparative pathology.

Once his staff is fully recruited, Hamm will begin a training program for research veterinarians who will come to Stanford as post-doctoral fellows.

"I'm very excited to be at Stanford because the university has always made such a strong commitment to be the best," Hamm said. "The quality of investigators doing research here is so high, and then to have the best laboratory animal facility could make a real impact on research."

He stressed that animal research is very important in the discovery process since virtually every new surgical procedure is first tested in animals for feasibility and safety and new medications undergo extensive testing in animals before humans are allowed to use them.

Prior to his four-year stint at the toxicology institute in North Carolina, Hamm served as an expert consultant and acting chief of the toxicology branch of the carcinogenesis testing program at the National Cancer Institute. Under his direction, Hamm said, several hundred chemicals were tested to determine if they caused cancer and to establish the level of exposure to humans that would be safe.

Hamm would like to do future research in whether some of these chemicals might also be a factor in heart disease.

He also wants to pursue another area of research in atherosclerosis.

"We have shown that behavior—stress—can lead to heart disease in monkeys, and we believe also in humans," Hamm said. I'd like to research what might be the basic mechanism why stress influences the development of heart disease."

Hamm said while his own research, the planned training program for postgraduate veterinarians, and the supervision of the Research Animal Facility's staff are important parts of his work responsibility, his primary function is the care of the research animals themselves.

8-2-85

-more-

"We make every effort to keep the lab animals healthy and happy," Hamm said. He added that air is recycled 20 times each hour, the animals' food routinely inspected for contamination, and the room temperature is kept consistently comfortable.

"Since we know that stress is a factor in disease, it's an important part of good research to make sure the lab animals are as healthy as possible," Hamm said.

He said the level of light is controlled since the amount of light can affect an animal's physiology.

All animal research projects are reviewed by a 10-member panel, which includes Hamm, other scientists, as well as community members and an outside veterinarian. The panel meets once a month.

Hamm, who is a diplomate of the American College of Laboratory Animal Medicine, said as a veterinarian, he decided to go into research "because my primary interest is in prevention of disease, rather than treatment."

Hamm said in addition to his work, he is extremely proud of his 17-year marriage to Diane Mauck and of their son, Jon, 15. The family also includes a 3-year-old springer spaniel named "Buddy."

Hamm enjoys cross-country sking and hiking with his family, trout fishing, and stamp and coin collecting. He is an avid genealogist, and spends one or two hours at night "writing people I've never met, trying to trace our roots."

"There are many ways our lives can make a difference," Hamm said. "I feel very fortunate to be doing work that I think is very important. When I'm 60, I think the things I'll be most proud of will be my marriage, my son, and the students I've helped train who hopefully will be doing research that makes a difference in our quality of life on this planet."

SCIENTIST SAYS NEW FACILITY MAY MAKE RESEARCH POSSIBLE

STANFORD—

Dr. Gerald Reaven believes that Stanford's new Research Animal Facility I (RAFI) may make the difference between whether a key portion of a project studying aging will be funded or discontinued.

Reaven and colleagues are attempting to determine whether many of the typical signs of aging, such as lack of glucose (sugar) tolerance in the body, are inevitable or can be avoided or minimized by such controllable factors as exercise or diet.

Reaven, an endocrinologist and professor of medicine, said he was told by the National Institute on Aging (NIA) that the portion of his grant earmarked for rat studies would not be renewed unless the investigations were carried out in the new $11 million facility.

Reaven said the scientists responsible for funding the project were concerned that the rats could come down with infections or diseases during the two year study, adding an extra variable to the research which could alter results.

The new facility contains features which are intended to minimize the risk of infection, including a double distilled water supply, a steam cleaning system which sterilizes cages, and extensive filtration in the air supply. Animal care areas are located below ground which enables personnel to carefully monitor and control the environment, explained Dr. Thomas Hamm, the veterinarian in charge of the facility.

Reaven and a principal colleague on the rat study, Dr. Andrew Hoffman, assistant professor of medicine/endocrinology, both said they won't know for sure whether they will receive funding for about three months.

"But they (NIA) made it quite clear that funding for the rat studies was predicated on having the new facility available," Reaven said.

The rat study is part of a project entitled the "Endocrinology of Aging," which has been funded by the NIA for the past six years. Current funding is approximately $400,000 a year, Reaven said, who along with colleagues had applied for a four-year renewal of the grant to take effect next April.

In the first six years of the project, the Stanford team has already learned that such signs of old age as lack of glucose tolerance are not inevitable but directly related to obesity and a lack of exercise—lifestyle factors which can be corrected.

Now the team wants to test other endorcrine functions, and also learn at what point in the life cycle corrective intervention is possible.

The rats which would be housed in Stanford's new animal facility play a crucial role, Reaven said, because they enable the scientists to study the entire life cycle in two years, rather than waiting many decades to determine the effect of aging on individual people.

He explained that a 2-year-old rat is equivalent in terms of aging to an 80-year-old human. If the rat is studied from adolescence at about two months, a complete lifespan can be tracked.

Reaven also said that rats are important to the study because scientists can examine specific organs, such as the pancreas. This could only be done in humans by autopsy he explained, "and by then you have deterioration which could affect the results."

Appropriate human studies are also involved with the project, and Reaven, who serves as director of the geriatric department at the Palo Alto Veterans Administration Medical Center, said those results will be correlated and analyzed when all the data have been collected.

PATHOLOGIST CARRINGTON DIES OF CANCER

STANFORD—

Dr. Charles Robert B. Carrington, an associate professor of pathology and internationally recognized authority on lung disease, has died after a year-long illness. He was 50.

Carrington, who died Wednesday (Sept. 25) of cancer in a local hospital, had served on the Stanford faculty since 1975. He was director of Stanford's Autopsy Service until he became ill nearly a year ago.

A colleague, Dr. Klaus G. Bensch, said Carrington was "internationally renowned as a clinical researcher and an outstanding diagnostician and teacher."

Because of his expertise on environmental factors and their relation to lung disease, Carrington was widely sought as a consultant on expert panels, including federal advisory committees.

Since 1979, he served as chairman or a member of the Secretary of Health, Education and Welfare's Mine Health Research Advisory Committee, a federal group dealing with such environmental safety hazards as black lung disease.

Carrington, a native of Illinois, graduated from Cornell University Medical College in 1960 and was a resident at Yale University Medical Center.

Before coming to Stanford as a tenured associate professor in 1975, Carrington served on the faculties of Yale University, the University of California, San Diego; and Boston University.

Carrington is survived by Pat, his wife of nearly 30 years. He is also survived by his father in Illinois and his brother, a Colorado attorney.

No services are planned.

SALMON HORMONE TESTED FOR OSTEOPOROSIS TREATMENT

STANFORD—

Scientists at Stanford University Medical Center are testing a hormone found in salmon to determine its effectiveness in retarding the effects of osteoporosis in older women.

Osteoporosis is a bone-degenerating disease, triggered by a lack of calcium, which affects about 20 million post-menopausal women.

Stanford is one of 10 medical institutions throughout the country at which the naturally occuring hormone, called calcimar, is undergoing final clinical testing required for approval by the Federal Drug Administration. The salmon hormone, similar to calcitonin in humans, is thought to affect calcium levels and bone metabolism in a way that decreases bone loss, researchers said. This may cut down the symptoms of osteoporosis, they added.

Calcimar "is not at present thought of as a cure for the disease, but rather as a treatment to prevent — slow down any further deterioration," said nutritionist Dr. Gail Butterfield, who is co-directing Stanford's clinical trials with Dr. Robert Marcus, associate professor of clinical medicine and director of the Geriatrics Research Education Clinical Center at the Palo Alto Veterans Administration Medical Center.

In order to test the drug, the scientists are seeking 30 post-menopausal women to volunteer for a three-year study. The women should be over age 45, and should already have experienced some bone deterioration. They should not be taking estrogen, a common therapy prescribed to combat the effects of osteoporosis.

Women who qualify for the study will be divided into two groups: one that will receive the experimental drug and one that will serve as a control group. All participants will undergo physical examination including blood tests and spinal X-rays. Follow-up checks will be required every three months. All procedures will be free of charge.

Considered one of the worst effects of menopause, osteoporosis causes bones to become thin and brittle, taking on a honeycomb consistency, Marcus said. Weakened vertebrae collapse under body weight, causing the stoop known as dowagers hump that older women develop. More than one million fractures each year occur in osteoporosis victims, at a cost of nearly $4 billion. About 15 percent of women with hip fractures die within three months, Marcus added, because of complications, such as pneumonia, blood clots and stroke, due to immobilization.

Women can help prevent osteoporosis early on in life through proper diet, exercise and other health-oriented habits such as not smoking, Marcus said. Calcimar, however, may keep the effects of osteoporosis from becoming more severe for those women who are afflicted.

For more information or to volunteer for the study, call (415) 493-5000, ext. 4572 from 1-4 p.m. weekdays.

BAGSHAW RECEIVES GOLD MEDAL FOR CONTRIBUTIONS TO CANCER THERAPY

STANFORD—

Dr. Malcolm Bagshaw, chairman of the radiology department at Stanford University School of Medicine, has been named the 1985 Gold Medal Award recipient of the American Society for Therapeutic Radiology and Oncology (ASTRO).

He will receive the award and deliver an honorary luncheon address at the Society's annual meeting Oct. 1 in Miami Beach.

The Gold Medal, the highest honor the Society bestows, recognizes individuals who have made outstanding contributions to the fields of radiation therapy and oncology.

Bagshaw was cited for his "distinguished service and contribution to medicine" and to the Society, a national organization of radiologists and oncologists, of which he is a past president.

Bagshaw is an international authority on the use of the linear accelerator against a variety of cancers, including prostate tumors, infant retinoblastoma (an eye tumor), ovarian cancer, and mycosis fungoides, a cancer of the skin.

His special field of expertise is the treatment of prostate cancer, the second most common cancer in American males, accounting for 60,000 new patients and 30,000 deaths each year.

In clinical trials directed by Bagshaw since he joined the Stanford faculty in 1956, more than 900 patients with prostate cancer have been treated with a 75 percent survival rate, forming the largest group of such patients in the world to have been treated at a single medical center with the linear accelerator.

He has also been a leader in studying techniques for enhancing the effectiveness of radiation therapy and in the search for new forms of anti-cancer radiation. He was an early proponent of the use of chemical agents to augment the radiation response, and he has been a leader in the effort to develop negative pi-meson radiation treatments for deep-seated tumors.

Bagshaw has directed the division of radiation therapy at Stanford Medical School since 1960. He became chairman of the radiology department in 1972, and currently holds the Catharine and Howard Avery Professorship.

He has received a number of honors and awards, including the American Cancer Society's 1984 Medal of Honor.

MEDICAL CENTER TAKES STEPS TO COUNTER ROCKETING PRICE OF INSURANCE

STANFORD—

In 1975, the cost of malpractice liability insurance for Stanford University Medical Center was $500,000 per year. When officials recently were told that their malpractice insurance bill would be $5.5 million as of Oct. 1, they decided to make changes.

The Medical Center has chosen to go to a form of "self-insurance," paying less in premiums but increasing the deductible per case from $50,000 to $250,000.

"We felt something had to be done because between January and October of this year alone, Stanford's malpractice premiums skyrocketed from $2.7 million to $5.5 million," said Donald B. Tower, executive director of the Faculty Practice Program. "Going to a quarter-million-dollars deductible was an important decision for us."

In addition, the type of insurance coverage has been changed from an "occurrence" basis policy to a "claims made" policy, Tower said.

Under "occurrence" policies, premiums are pre-paid to cover claims regardless of when they are reported. For example, if someone is born with birth defects but doesn't file suit until the age of 18, that claim would be covered under the previous policy.

Under the "claims made" system, premiums are figured on a cumulative basis. Claims which occurred in the current year but are not filed until later years, such as the example above, are deferred in computing the premiums.

The first year such a policy is in effect, premiums would be based only on claims in that calendar year. The next year, they would be computed according to the claims filed in the years 1985 and 1986. The third year, they would be based on claims from 1985, '86, and '87.

By the fifth year, analysts have told Stanford, the cost of premiums probably will be as large as premiums under the old type of policy, but the advantage is that Stanford University Medical Center would be paying out less money right now, and can use that cash for other purposes.

Instead of paying $5.5 million in premiums now, the Medical Center will budget $3.4 million for malpractice insurance from Sept. 1, 1985, to Sept. 1, 1986. That amount includes $1.9 million for insurance premium, $1 million for "tail coverage," approximately $400,000 to cover deductible losses, and $100,000 for defense costs.

"Tail coverage" is a reserve amount held by the Medical Center to cover whatever future costs would be incurred if Stanford changes to a new insurer or a fully "self-insured" plan, said Robert M. Beth, Stanford University's director of risk management. The reserve would be needed, he said, to cover claims which occurred in the years the "claims made" policy was in effect, but were not filed until later.

He added that the decision to change the type of insurance from "occurrence" to "claims made" was made by officials from Stanford University Hospital, the Faculty Practice Program, and the Medical School. The committee making the recommendation was chaired by Carole Price, associate director, who was instrumental in establishing the first hospital-wide, risk management-quality assurance system.

During the past 26 years, Beth said, Stanford's malpractice insurance premiums were $23.8 million, while losses, defense costs, and expenses were $23.7 million.

Stanford is continuing to evaluate malpractice insurance alternatives, including reviewing and revising risk management procedures, Beth said.

Officials say the national "malpractice insurance crisis" impacts medical costs and the physician's choices of tests and treatment.

The American Medical Association (AMA) estimates that "defensive medicine"—physicians ordering extra health care procedures and diagnostic tests in order to protect themselves against potential suits—raises health care costs between $15 billion and $40 billion per year.

The insurance industry argues that the increases in premiums are the result of industry-wide losses, which reached $21 billion in 1984, the largest in history and the fourth year in a row of record losses. Underwriting losses for malpractice specifically amounted to $386 million last year, with New York cases accounting for $129 million of that deficit.

The AMA also reports that the number of malpractice claims has more than doubled in the last decade. Court awards of $1 million or more have gone from three in 1975 to 70 in 1983, the AMA says, even though some states have instituted stopgap measures:

For example, the amount of money that can change hands in a malpractice suit in California is limited by law. Lawyers' contingency fees are 40 percent of the first $50,000 of a malpractice award, a third of the next $50,000, 25 percent of the next $100,000, and 10 percent of anything more than $200,000. No pain-and-suffering award can exceed $250,000. Awards of more than $50,000 can be paid in installments, which are discontinued if the patient recovers or dies.

"The malpractice rates affect every hospital," said Dr. James F. Silverman, chief of staff, "but Stanford is probably in better shape than most places because we are a teaching hospital, and so we have built-in quality assurance. There are a lot of people here who review medical decisions.

"That scientific edge offers more opportunities for cures, but it still doesn't mean that everything is curable. Patients should be aware of that. They can't enter the hospital with serious and complex medical problems and expect to leave feeling perfect. If they leave feeling 50 percent better, that may be an excellent result. Patients have to change their unrealistic expectations."

Being a teaching hospital has its drawbacks too, said Silverman.

"It means that patients who come to Stanford may have more serious medical problems than patients at the average community hospital," Silverman said, "It also means that the patients haven't had a chance to develop a rapport with the physicians treating them in the way they generally do with their community physicians. A patient who has known a physician a long time and had a good relationship with that physician for years is less likely to sue if something goes wrong than if they've just met the physician."

One area where the courts have made huge malpractice awards in recent years has been in claims relating to obstetrics-gynecology.

Along with advanced techniques, such as ultrasound for fetal monitoring, have come potential risks, said Dr. Kent Ueland, acting chairman of Stanford's Department of Gynecology and Obstetrics.

"People feel they should be guaranteed a perfect outcome with childbirth and that isn't always possible," said Ueland, "but we do have a good review and monitoring system of cases that come to Stanford, and doctors who are weak in interpreting the results of certain procedures are required to have consultants when they use those procedures."

Ueland said there are many ways of reviewing physicians' performances, including nursing incident reports and periodic reviews of procedures and patient results by members of the quality care committee and the practice privileges committee.

Robert Kessler, associate professor of clinical surgery (urology), is chairman of the care review committee, and Karen Axnick is director of the care review-risk management department, "and both are actively involved in the identification, review and resolution of quality of care issues throughout the Medical Center," said Carole Price.

"Because of all the review at Stanford, the chances of having problems here are slimmer, I would say, than at the average community hospital," Ueland said. "We limit physicians' practice privileges if they aren't proficient in certain areas. Some doctors are asked to get consultants when they do fetal monitoring. Others are restricted from using mid-forceps. Some aren't allowed to do vaginal breech deliveries."

In recent years, modern technology has enabled hospitals to improve care and results, and allowed patients to return home sooner than in the past. According to Sheldon King, patients at Stanford University Hospital were staying an average 6.8 days in the fiscal year ending Sept., 1984, and in the fiscal year ending Sept., 1985, the average was about 6.5 days.

Donald Tower pointed out that because of changing medical technology, advances in drug therapy and improved diagnostic and treatment methods, much care that was rendered inside hospitals 20 years ago can now be provided on an ambulatory basis at lower cost. Still, he said, one major problem in terms of cost containment, is the size and the frequency of malpractice suits.

"Twenty years ago, patients generally didn't sue their doctors unless there was a really obvious case of malpractice," said Tower. "Today, people sue if they leave a place 50 percent better instead of 100 percent. I think patients need to understand that doctors aren't miracle workers, and they shouldn't expect unrealistic outcomes."

Tower added that he thinks the care at Stanford is "as good or better than anyplace in the country," and because of that, he supports the change to "self-insurance."

"Rather than pay more than $5 million for malpractice premiums, and let the insurance companies use our premiums to pay their losses for the crash of a jumbo jet somewhere, I think we're making a wise decision to take the malpractice risk and earn the investment income from the money we would have been paying out in premiums," Tower said. "Our doctors practice quality medicine here, and I think we'll end up saving lots of money with a self-insurance program."

SAME-DAY SURGERY UNIT IMPROVED AT STANFORD HOSPITAL

STANFORD—

Patients don't have to wait for the Hospital Modernization Program (HMP) to be completed to begin benefitting from an improved Same-Day Surgery unit at Stanford University Hospital.

Carole Price, associate hospital director and administrator responsible for the project, said the new ambulatory surgery facility will begin service Monday, Sept. 23.

The unit is intended for use until a permanent one is built as part of the HMP.

There is a significant trend toward increased use of outpatient procedures, Price said, because they offer a more economical approach to less complicated procedures. They are geared toward the surgical patient not expected to require post-operative overnight care in a hospital.

In some situations, of course, admission to the hospital may be required after outpatient surgery, and "that's the advantage of having the unit as part of the hospital—which is right there for back-up as needed," Price said.

"As physicians we are looking forward to the conveniences that this new facility will offer not only to those of us who will be performing surgery there, but more importantly, to our patients," said Dr. John Collins, chairman of the Department of Surgery.

"Shorter hospital stays make surgery more economical and convernient for patients, and we're glad that our hospital can be a part of the evolution which is making this concept more prevalent," Collins added.

"Those of us in the community feel that this is a step in the right direction and will benefit our patients. I'm pleased with the enlargement of the unit, which will facilitate caring for our patients in a more timely fashion," said Dr. William R. Fielder, a Palo Alto general surgeon who operates at Stanford.

Advantages of the interim unit, Price said, include the comfortable accommodation of up to 12 patients on gurneys and reclining chairs. The old unit had only four adult slots.

"Services needed for the patient prior to surgery, such as blood tests, will be conducted in the unit, saving the patient trips to various labs or other areas of the hospital," said Claire Mailhot, director of operating room services.

To supplement the center's operating rooms where surgery is to be performed, the facility offers two minor treatment rooms. The two multi-purpose treatment rooms will allow space for pre-operative assessment of patients, including such diagnostic procedures as YAG laser therapy, and endoscopy/bronchoscopy, Mailhot said. Minor surgical procedures requiring local anesthesia may also be performed there.

"This provides a centralized place to do small biopsies, excisions of small masses and small basal cell cancers, and some minor ENT procedures," said Mailhot.

Patients coming for ambulatory surgery will be admitted, and have their lab work and tests done right at the unit, rather than having to go elsewhere for each function, she said.

The renovated facility also includes a recovery area, two bathrooms, one shower, lockers for patients, and a family waiting area (located conveniently close to the cafeteria). It will be well marked, Mailhot said, with easy access for patients, including designated parking (at no charge).

Price said starting in November physicians will be able to make a single phone call to arrange for both operating room scheduling and room reservations of surgery patients. This concept of "one call does it all," Price said, is an attempt to improve convenience and service to physicians.

The facility will open 5:30 a.m. weekdays. Clinical nursing coordinator is Lorraine Pucher, who remains CNC for same day surgery and the recovery room.

Mailhot said members of the public interested in touring the facility or making general inquiries about same day surgery should call (415) 497-5620.

STANFORD — MAXICARE SIGN UNIQUE AGREEMENT

STANFORD—

In keeping with the changing trends in health care, Stanford University Clinic has signed an agreement to provide medical services to subscribers of Maxicare, one of the largest health maintenance organizations in the country.

"This is one of the few agreements between an academic institution and an HMO," said Donald B. Tower, executive director of the clinic. "We took this step because we recognize the soaring cost of health care is of concern to everybody. Employers are looking for ways to control expenses, and HMOs are one alternative to the traditional fee-for-service system."

The people who belong to HMOs pay monthly premiums that essentially enable them to get all the medical care they need with no additional costs, while the providers of care receive a fixed monthly "capitation payment" to pay for the cost of all care. This payment methodology produces a financial incentive to physicians to keep HMO enrollees healthy.

Last year, total spending for medical care in the United States was reported to be $322 billion, equal to 10.2 percent of the Gross National Product. The cost of health benefits cuts into employees' take-home pay, raises product prices, and impacts on the ability of American business and industry to compete in international markets.

By 1990, analysts predict, an estimated 15 percent or 40 million Americans will be members of prepaid health plans, as opposed to individuals covered by commercial insurers.

According to Dr. Fred W. Wasserman, chairman of the board and chief executive officer of Maxicare, "Although HMOs have been around for many years, their recent acceptance and growth in membership can be attributed to their ability to arrange health care in a cost effective manner by providing many surgical services on an out-patient basis, reducing the incidence of unnecessary surgery, covering periodic physical examinations and routine office visits, and by keeping members healthy through health education programs."

Members of Maxicare would pay a maximum of $2 for office visits to their doctors, and no claim forms are required, said Phillip L. Robbins, marketing director of Maxicare for Northern California.

The affliation with Stanford University Clinic is unique for both Maxicare and Stanford.

"I know of only a few other academic institutions affliated with an HMO," said Tower. "One is the Harvard Community Health Plan based in Massachusetts. That is affliated with Harvard University physicians. Another leader in this area is Washington University in St. Louis, which developed its own HMO several years ago."

Robert Dienes, executive director of Maxicare for Northern California, said that while it has contracts with individual physicians who are affliated with universities in different parts of the country, this is the first agreement between an academic institution and Maxicare. He added that 211 Northern California companies currently offer Maxicare to their employees. They include the Bechtel Power Corporation, Crocker National Bank, Honeywell, Inc., Neiman Marcus, and Pacific Telephone.

"When you mention the Stanford Medical Center to a lot of people, I think most of them think first of the world-renowned specialty care here," said Tower, "but it's important to note that we also have some of the finest primary care physicians available anywhere."

The clinic's professional staff includes 280 faculty physicians and surgeons, including 10 devoted to primary care.

"These are primary care doctors that patients come to develop a personal, one-to-one relationship with," said Tower. "These internists and pediatricians provide personalized, routine care, as well as acute care services when necessary. If a consultation with a specialist is needed, the primary care physician coordinates it so there's optimal continuity of care and cost effectiveness."

Stanford University Clinic is a practice with 140,000 patient visits per year, serving both the local and regional populations in Northern California and the West.

Within the last few years, there has been major renovation to modernize Stanford's clinic facilities.

The Maxicare plan covers primary care physician services, outpatient ancillary services and specialty physician services at Stanford. It also covers hospitalization in Stanford University Hospital.

Stanford's faculty practice physicians also participate in the Blue Cross Prudent Buyer Plan and Blue Shield's Preferred Plan. Patients insured by these plans must be seen by "preferred physicians" to receive maximum benefits.

UNUSUAL THIRD WORLD DISEASE STRIKES SOUTH BAY MAN

STANFORD—

A rare case of parasites in the brain, a disease normally confined to third world countries, was revealed last week to have struck a Northern California resident now being treated at Stanford University Hospital.

The 22-year-old victim comes from a small village in Mexico. His disease is not contagious, but it illustrates the risks of bad hygiene, said Dr. Carlos Camargo, associate professor of clinical medicine who supervises the patient's care.

As more immigrants from rural areas in impoverished countries settle in the United States, Camargo added, American doctors may be introduced to diseases that are a legacy of primitive living conditions.

Miguel Garcia (not his real name, to protect his privacy) grew up drinking water from springs and rivers. There were no toilets or even outhouses in his village. He now carries the larvae of a pig tapeworm in his brain.

It is unusual for a human to be infested with the immature form of the worm, Camargo explained. More commonly, people will harbor the adult parasite in their intestines.

Infections with the adult worm, which give mild symptoms such as anemia or stomach cramps, are easily cured, Camargo said. But getting rid of larvae, he said, is more difficult.

Garcia, now living in a South Bay town, came to his local hospital complaining of a severe headache that was getting worse. Lights bothered him, he saw halos around objects, and he also had a stiff neck.

A spinal tap revealed evidence of severe inflammation of the tissues around the brain. He was rushed by the Lifeflight helicopter to Stanford.

"When we looked in his eyes (with an opthalmoscope), we saw clear evidence of severe pressure within his head," said Dr. Barbara Widom, the resident physician who first saw Garcia when he arrived at Stanford near midnight.

An emergency CT scan revealed clustered dark splotches of fluid-filled cavities, or cysts, within the patient's brain. A few older cysts, now calcified, could also be seen.

Knowing the patient was originally from rural Mexico led the attending doctors to suspect that the cysts represented the rare, larval form of the pig tapeworm disease, which is called cysticercosis. The next morning, Stanford neurologists confirmed the diagnosis.

A shunt surgically placed inside Garcia's head now drains excess fluid into his abdominal cavity.

Without this immediate step to decompress the brain, Widom said, Garcia would have suffered brain damage.

9-16-85

-more-

"He seems fine neurologically," she said. "Our main concern was that he would lose his vision.

Garcia's visual problems have cleared, however, and his headaches are relieved, said Camargo, who converses with the patient in Spanish.

According to Widom, the patient "could have subtle deficits (in mental ability) that we're not aware of," but, she added, as far as Camargo and other Spanish-speaking care givers can tell, Garcia has suffered no permanent harm to his brain.

He has been placed on steroids in preparation for the drug therapy he will receive.

Praziquantel is the only compound available to kill the tapeworm larvae, Camargo said. It works, but debris left by the mass death of the parasites can provoke more swelling and inflammation within the brain. Steroids hopefully will avert this reaction, but Garcia will have to stay hospitalized so the doctors can carefully monitor his response.

In the more common infestation with the adult parasite, Camargo said, larvae living in the flesh of pigs can find their way to the human gut where they attach and grow into worms, if infected meat is eaten without being thoroughly cooked.

"Pork should always be cooked until gray, with no pink left," which will kill any parasites, Camargo said.

Larval infections are acquired differently.

Eggs laid by the adult worm are carried into the ground by the host's feces. From the soil, the eggs can contaminate drinking water.

Only by swallowing the eggs can people get the larvae in their body tissues.

STANFORD OPENS SPECIAL CLINIC TO HELP BREAST CANCER VICTIMS

STANFORD—

A new multidisciplinary, consultative breast cancer clinic provides the final link in Stanford University Medical Center's breast cancer treatment program, said its director, Dr. Frank Stockdale, professor of medicine.

The new clinic, scheduled to open Sept. 27, provides an entry point for patients to be treated at Stanford.

"With this new clinic we now have a very comprehensive breast cancer treatment program," Stockdale said.

Unique to the region because of its multidisciplinary make up, he continued, the clinic provides women at high risk or recently diagnosed with breast cancer one central place at which they can undergo all necessary diagnostic procedures and be informed of all possible treatment options before treatment is initiated.

"If a woman gets breast cancer, she typically has to go to several physicians in order to learn about and get treatment," Stockdale said.

Women can come to the new clinic, staffed by breast cancer specialists including oncologists, surgeons and radiologists, for evaluation and consultation of all treatment options, Stockdale explained. The patients will then be referred to the appropriate Stanford clinics for treatment.

"Often what happens is one physician will initiate a treatment that may not be the optimal one," he added. "What we want to do is to be able to design for each individual a treatment program that takes into account all considerations."

The new clinic is "only part of a larger program for the diagnosis and treatment of advanced breast cancer already active in the medical center," he said.

Other services it provides include evaluation of pathological slides, mammography, radiological imaging, hormone receptor assays and breast self-examination training. Special programs including individual counseling and support groups will also be available to help patients cope with the emotional side of their illness.

FOR IMMEDIATE RELEASE

MCDEVITT WILL BECOME NEW MICROBIOLOGY CHAIRMAN IN JANUARY

STANFORD—

Dr. Hugh O. McDevitt, Joseph D. Grant professor of medical microbiology and medicine, has been appointed chairman of the department of medical microbiology of the Stanford University School of Medicine, Dean David Korn has announced.

The appointment will be effective January 1, 1986.

McDevitt, 55, noted for his work on the genetic control of the immune system, has been on the Stanford faculty since 1966. He will succeed Dr. Stanley Falkow, professor of microbiology, who served as chairman since 1981. Falkow, widely recognized for his work on the application of modern concepts and technologies of molecular biology to problems of human infection and development of vaccines, will return to full-time research and teaching.

Medical microbiology is the third basic science department of the medical school to adopt a system of rotating chairmanships, explained Korn.

The dean recently announced a new policy which anticipates that in preclinical departments, the rotation of the chair will "become the usual and desired practice in order to promote stability of academic leadership and continuity of programmatic development."

Until recently, when departmental chairs became vacant, the prevailing practice in the school was to seek replacements from the outside. The new system of rotating chairmanships has been successful in departments such as biochemistry and cell biology, Korn said.

A Stanford undergraduate, McDevitt received the medical degree from Harvard Medical School. He was promoted to professor of medicine at Stanford in 1972 and received an appointment in the department of medical microbiology in 1978. During the 1970s he headed both the division of immunology in the department of medicine and the clinical immunology laboratory at Stanford University Hospital.

He was elected to the National Academy of Sciences in 1977 and to the National Institute of Medicine in 1983.

In recognition of his work, McDevitt has received the Borden Award for oustanding research from the Association of American Medical Colleges in 1977. In 1981 he received the Passano Foundation Award for his research on "the relationship between the immune system, histocompatibility antigens and human disease."

—30—

SAUL ROSENBERG APPOINTED TO ENDOWED CHAIR

Dr. Saul A. Rosenberg, professor of medicine and radiology, has been appointed the Maureen Lyles D'Ambrogio professor in the Stanford University School of Medicine by the board of trustees.

Rosenberg, 57, chief of the division of oncology of the department of medicine, is internationally known as an innovator in the field of clinical oncology.

The D'Ambrogio endowed professorship was established in 1970 by the late N.J. D'Ambrogio of Carmel, as a memorial to his daughter, Maureen, who died of cancer in 1967. Cancer research pioneer Dr. Henry S. Kaplan became the first holder of the chair in 1972. Kaplan died in 1984.

Rosenberg, a graduate of Western Reserve University School of Medicine teamed up with Kaplan and other colleagues at Stanford in the early sixties. They helped develop an effective treatment strategy combining drugs, radiation and surgery, that has dramatically improved survival rates for Hodgkin's disease patients. Nearly 80 percent of these cancer patients, when prcoerly treated, can now be cured of the disease.

He is a recipient of the 1984 David Karnofsky Award from the American Society of Clinical Oncology for innovative clinical advances made in oncology during recent years.

Rosenberg heads a major research program which brings together both clinical trials and laboratory studies in an effort to improve the treatment of patients with all types of malignant lymhoid tissue tumors.

Rosenberg also holds the American Cancer Society's professorship in clinical oncology, awarded by its California division.

MEDICAL SCHOOL ADOPTS UNIQUE APPROACH TO ATTRACT MINORITIES

STANFORD—

A unique summer program to increase the number of minority and economically disadvantaged students has been under way at the Stanford University School of Medicine.

Started a year ago in response to a sudden decline in enrollment of minority students, the program gives students an early entry and orientation into Stanford's educational environment and prepares them for experiences not only in clinical medicine but in research as well, according to associate dean Dr. Robert W.P. Cutler. The program is opened to students of primarily hispanic, black, native American, and low income backgrounds.

The program is important, Cutler explained, because Stanford is committed both to training physicians for the scientific practice of medicine, and for biomedical research and academic careers.

Physicians from minority backgrounds are seriously under-represented on medical school faculties, Cutler said. The Stanford curriculum is designed to develop in all students the capacity for leadership in the clinical practice of medicine and to prepare them for research and teaching in the various branches of basic, clinical and social medicine.

"Although a small fraction (about 15%) of our students pursue a career in full-time research, we have little doubt that these research experiences taken by the majority contribute to their maturation as competent, scientifically-oriented physicians," said assistant dean Dr. Fernando Mendoza who, with assistant dean Dr. Roger Peeks, directs the new program under a three-year $331,000 grant from the Health Careers Opportunity Program of the U.S. Public Health Service.

An Office of Student Affairs analysis of those students who have not pursued research opportunities offered at Stanford has shown that about 75 percent are from minority backgrounds.

"We do not believe that these disadvantaged students are lacking in desire to enrich their education through research experience," said Mendoza. "Instead, many of these students have had to omit this important aspect of their educational program because they are often encumbered by a difficult struggle to do well academically during the preclinical years."

To counter these forces, Mendoza explained, the program offers an early matriculation, eight-week summer program in which students admitted to the school take courses in such subjects as biochemistry and histology coupled with research of their own choosing under faculty supervision.

In addition, the program offers educational assistance, counseling and individualized evaluations to insure a smooth transition into Stanford's medical environment during their first year.

Beyond the summer program, Stanford's efforts to increase the success of its affirmative action commitment includes continued support from tutorials to counseling during the preclinical and clinical years.

When the first class of seven students enrolled for the summer program, the results were very positive, Mendoza said. All students did well in their courses and their research experience was received favorably. This summer's class agrees.

9-16-85

-more-

"The summer program gives us a chance to get two classes out of the way, to start on research projects that are of interest to us, and to adjust to an environment that is very different, much more affluent, than what most of us are used to," said Abe DeAnda, 23, one of the students in the program.

Before entering medical school, DeAnda worked as a mechanical engineer, designing automated test equipment. He would like to apply those skills and the skills he gains as a doctor to design artificial organs.

Adrienne Randolph, 23, who is working with researchers in the study of nerve regeneration, said, "The summer program has been very important to me, because it helped me make a social adjustment to Stanford. If I hadn't started early, I probably would have had a multitude of problems my first quarter, but the fact that I've met people and made friends during the summer will make the fall much easier, I know."

Miriam Larios, 22, was impressed with the fact that Stanford offers a five-year curriculum, whereas many schools require students to complete their medical education in four years. Larios is particularly interested in developing health and nutritional programs for Mexican-American children.

"There's a real need for minorities in health education," Larios said. "If you've got a dream, pursue it. Apply to medical schools. Keep applying if you're not accepted right away. Don't let anyone discourage you."

Abdullah Brooks, 29, agreed. "Many minorities might have felt medical school was out of their league, not a real option for them, but there are real opportunities now for minorities who want to go into science," said Brooks, whose research interests are malnutriton and certain parasitic diseases that are widespread in Africa, where he lived for many years. "The competition in medical school is intense for the truly qualified, but there are several things that can be done. Apply for outside loans and grants. Compete for fellowships and other grants and scholarships."

Brooks, who is married and the father of three children ranging in age from two to nine, said time management is an important aspect to being a successful student. "I think it's important to have realistic expectations, to understand that there are tremendous pressures in medical school," he said, "but don't be so discouraged by the problems that you don't follow your dream."

Stanford's medical school has been involved in the recruitment and education of disadvantaged students since 1969. They have comprised 15 to 20 percent of the entering class. According to a 1983 survey published in Health Careers Network, the percentage of minority students has been higher at Stanford than in any other U.S. medical school.

Recently, however, the school's minority enrollment declined to 12 percent. Mendoza attributes it to several factors explained by student questionnaires. They include misperceptions of financial cost and of Stanford being for those students interested only in research.

"But cost, viewed in context with the average indebteness of medical students in other schools show Stanford to be very competitive, because scholarship support is based on financial need and there is a tuition limit of 13 paid quarters," Mendoza said. "This results in an average indebteness of about $26,000 for Stanford students as compared to $24,000 for those attending state schools. And students can decrease their debt by research and teaching assistanships which provide tuition credits at Stanford."

The second misconception can be dispelled by statistics which show that about 85 percent of Stanford's medical graduates enter clinical practice, Mendoza said. "Research is an important part of the medical school curriculum to facilitate the teaching and learning of scientific medicine, to stimulate critical thinking and provide a wider range of professional career opportunities."

PALO ALTO PHYSICIAN DISPLAYS UNDERWATER PHOTOGRAPHY IN HOSPITAL

STANFORD—

Man and the ocean have been intertwined in Dr. Alfred Spivack's life for many years.

The Palo Alto cardiologist taught swimming and boating to help pay his way through college and medical school. Now, his active interest in scuba diving and underwater photography is an active adjunct to his interest in sports medicine and underwater physiology.

Spivack, a clinical professor of medicine at Stanford, directs the sports medicine course at the medical school and personally teaches the section in diving medicine. During vacations and off hours, he takes his cameras underwater in such locations as the Philippines, Caribbean and the Red Sea, and then processes and prints his pictures himself to ensure quality.

Members of the public will have a chance to see 38 of Spivack's photographs in a display mounted outside the Stanford University Hospital cafeteria from Sept. 30 through the end of the year.

Entitled "Rainbows of the Sea," the photo display is open free to the public. Spivack has donated several of the photographs from the exhibit to be sold to benefit the Hospital Modernization Program (HMP), the $114 million construction and renovation project.

Kristine Erving, community outreach coordinator in the hospital's Department of Community and Patient Relations, said the photo display is the first of several by Stanford-affiliated physicians which will be held while HMP construction continues through the fall of 1987.

"We found there are several extraordinarily talented photographers among our medical staff," Erving said. "So we thought displaying their works during the time of construction was an unusually appropriate way to ensure a pleasant environment in our hospital while giving members of the broader community an opportunity to view an extracurricular dimension of our medical staff," Erving said.

Spivack said he became interested in scuba diving shortly after he resigned as director of the hospital's Cardiac Care Unit in 1975 to concentrate on his private practice and voluntary teaching duties. Once underwater, "I wanted to bring back some of what I saw in pictures," he said.

The physician's photographic work is varied, and includes scenic vistas of the underwater world, as well as closeup pictures focusing on color, shape and form.

Spivack's wife, Anita, is an interior designer who shares her husband's interest. "Her input is important in terms of artistic composition," says Spivack.

NURSING CHIEF WALKER ACCEPTS HAWAII POST

STANFORD—

Duane Walker, associate hospital director and director of nursing, will be leaving Stanford University Hospital Nov. 1, 1985 after seven years for a position as vice president of Queens Medical Center in Honolulu.

Walker's many accomplishments at Stanford range from successful recruitment of nurses during a nationwide shortage in the early 1980s, to launching one of the country's first nursing research departments, to the development of a clinical ladder for staff nurses by which they are promoted and rewarded "just as much for bedside nursing as they would be for management."

Under Walker's direction Stanford's nursing department this year launched a home care program.

A satellite B.A. nursing program in conjunction with San Jose State University was set up during Walker's tenure, as well as a satellite master's program at Stanford through the University of California, San Francisco.

Walker, himself a registered nurse, has worked towards opening the nursing profession's doors to both sexes. Although the field is usually perceived as "feminine," Walker insists that any profession can only benefit from the variety of contributions provided by men and women.

Before coming to Stanford, Walker, a native of Iowa, served as assistant administrator for patient care services at the University of Utah Medical Center. He received his undergraduate degree from Weber State College, Utah, in 1964 and his master of science degree in psychosocial nursing from the University of Utah in 1975. He served in the U.S. Army Nurse Corps as an inservice education instructor from 1966-68.

At Queens Medical Center, Walker said he will have administrative responsibility for the mental health center, outpatient clinics, cardiology, EKG, physical therapy, occupational therapy, rehabilitation, volunteer services, patient relations, social services, emergency, operating rooms, ambulatory surgery, and general nursing units.

The 569-bed hospital recently moved into a new 10-story building with many new facilities—similar to the upgraded facilities planned for Stanford under the Hospital Modernization Plan (HMP), he said.

HARVARD PHYSICIAN VISITS STANFORD AS KOVITZ PROFESSOR

STANFORD—

Dr. Edgar Haber, Harvard Medical School's cardiac unit chief, is Stanford University Medical School department of medicine's 1985 Kovitz Visiting Professor.

Haber will give a research seminar in cardiology, "Antibodies as *in vivo* diagnostic and therapeutic agents in cardiovascular disease," Wednesday, Sept. 25, at 4 p.m., in the cardiovascular research building library.

Haber will lead grand rounds and give the Kovitz lecture, "Fibrin-specific antibodies as potential diagnostic and therapeutic tools," Thursday, Sept. 26, at 8:30 a.m. in Fairchild Auditorium.

A reception honoring Haber will be held for department of medicine faculty, fellows and housestaff Sept. 26, at 5 p.m., in the department's library.

The visiting professorship was established in 1970 in honor of the late Dr. Louis Kovitz and his wife, Dorothy. The purpose of the professorship is to allow physicians of national or international prominence to give annual lectures, rounds and clinical pathological conferences on topics of medicine and surgery at Stanford.

Haber is the Higgens Professor of Medicine at Harvard, where he directs the M.D.-Ph.D. program in addition to his responsibilities in the cardiac unit. He is involved in many medical school and hospital committees, and chairs one on conflict of interest and commitment.

Haber serves on several editorial boards, and is editor-in-chief of *Hypertension*. He is involved with many professional societies, including fellowship in the American College of Cardiology and American College of Physicians.

Haber received an award for outstanding research earlier this year from the International Society for Heart Research and *The Journal of Molecular and Cellular Cardiology*.

For more information, contact Teresa Terry in the department of medicine, 7-5452.

POST MENOPAUSAL WOMEN SOUGHT AS VOLUNTEERS FOR STUDY

STANFORD—

Volunteers are being sought to participate in a Stanford University Medical Center study examining the role of biological factors such as hormone levels and aging on human sexual behavior.

Dr. Julian Davidson, professor of physiology, is seeking about 30 postmenopausal women with whom he can examine the effects of hormone replacement therapy. The women should be at least one year past menopause, and should not have had any hormone treatments for at least three months. They should be generally in good health.

Participants will receive a physical examination upon acceptance to the study. They will be required to come to about six appointments at Stanford during the three-month long study, during which time they will be administered either one hormone, a combination of hormones or a placebo. The effects of the hormone therapy will be monitored by questionnaires and physiological responses to erotic stimuli.

For information about the study, call Dr. Lin Myers at (415) 497-2432.

RETIREMENT FOR HENRY JONES MEANS EXPLORING NEW VISTAS IN RADIOLOGY

STANFORD—

Professor Henry H. Jones anticipates having the time to cash in on exciting advances in radiology as he retires from full-time duties at Stanford University School of Medicine.

At 68, Jones has spent 37 years with the university, having joined the radiology department as instructor in 1948.

For his retirement, he has drafted a three-page list of ideas to pursue, "though if you come by in six months you'll probably find me in front of the TV drinking beer," he quipped during an interview. Belying his light-hearted prediction are some serious thoughts for future teaching and medical sleuthing.

A colleague, Dr. Ronald Castellino, calls Jones "a skilled radiologist and one of our better teachers." Jones received the Henry J. Kaiser award for excellence in clinical teaching from the medical students in 1982.

Jones said he will continue his "formal classes which are very informal" for medical students and residents, and hopes to finally create a computerized order out of the controlled chaos of his files of x-ray films used in teaching.

"I plan to put my wife to work on that," he noted about the latter task. Since Proposition 13 closed the clinic at which his wife, a pediatrician, had worked, Jones said she has helped him prepare the Saturday morning conferences that he holds with pathologists and orthopedists. The weekly meetings have generated valuable teaching materials that he would like to organize so others can easily use them.

Meanwhile, he said, he will "keep his eye at the knothole" to follow the latest developments in magnetic resonance imaging (MRI) and synchrotron radiation. These sophisticated technologies were almost beyond imagination three decades ago when Jones, as assistant professor of radiology, struggled to improve ways of watching a beating heart with conventional x-rays.

In retrospect, his efforts at improving the efficiency of x-ray movies failed, Jones said, not because the potential wasn't there, but because "I didn't push hard enough. I didn't appreciate how you have to get the people and money together."

more

9-9-85

The experience, he said, taught him how frustrating it can be to work on "the edge of technology."

But, fascinated by that fast-moving edge, he now cites MRI as the most important advance in medical imaging that has occurred during his lifetime. "CT (computed tomography) opened the door to a tunnel," he said. "MRI has opened a door to a whole plain—it's mind-boggling."

And it may finally solve what has remained a mystery throughout his career. His main research interest has been the skeletal system, but details of the route blood takes through bones remain sketchy. Once a blood vessel dives into a bone, the trail it traces on an x-ray picture vanishes, as bones block x-rays, Jones explained.

Yet understanding the blood supply of bone may give clues as to why some fractures don't heal properly, or at all.

Though he has not yet pursued funding, and the ability to peer inside bones with the new methods is not yet fully explored, he expects that both MRI and synchrotron radiation "can make bone disappear, so we can get an idea of which way the blood is flowing."

The radio-frequency waves of MRI can penetrate bone. And, he said, the precisely tuned x-rays generated by a synchrotron can theoretically subtract calcium's signal, leaving behind an image of the vessels.

In past research, Jones has studied the nutritional requirements of embryonic bones grown in tissue culture, and he helped document the increase in bone mass that occurs in the playing arm of tennis professionals.

Other academic pursuits have ranked equally with work in the lab. "One of the most rewarding things I've done is pre-medical advising," Jones said. And according to his consecutively numbered student files, he has counseled 847 undergraduates who he describes, with tongue only partly in cheek, as "misguided enough to wish to become physicians."

"It is a demanding profession—it requires such an investment of time and energy," he said. To choose medicine, he continued, there should be "a direct, emotional commitment to patients."

Having started at Stanford before the medical school moved from San Francisco to join basic sciences on the Stanford campus, Jones has seen the medical school grow from "a relatively small place to a nationally recognized one" with a roster of "extraordinary people."

He received his M.D. degree from Yale University in 1943, spent his internship in New York and his residency in New Haven, and was a radiologist in the army for two years before coming to Stanford. He also served as Chief of Radiology at the Palo Alto VA Hospital from 1960 to 1972.0September 9, 1985

VOLUNTEERS NEEDED TO TEST INTERFERON ON WARTS

STANFORD—

Scientists at Stanford University Medical Center are looking for 10 volunteers to test the effectiveness of an interferon lotion in treating warts.

Volunteers must be in general good health and at least 18 years of age. They must have at least four warts that are no less than one-and-one-half inches apart.

Human warts, *verruca vulgaris*, are caused by a virus infecting the skin. Currently accepted treatments include using a lotion called Podophyllin, freezing with liquid nitrogen or surgically removing them. Interferon, an antiviral agent produced naturally by the body or synthetically manufactured, may be effective in combatting the wart-causing virus, the researchers believe.

Patients admitted to the study will receive a complete physical examination and blood chemistry tests at the beginning and end of their treatments. They will be required to come to the dermatology department daily for a three week period to have the interferon lotion applied. Those who complete the study will receive a $150 reimbursement.

To volunteer for the study, call Diane Wenner, clinical studies coordinator, at (415) 497-7944.

NATIONAL KIDNEY FOUNDATION HONORS STANFORD PHYSICIAN

STANFORD—

Stanford nephrologist Dr. Roy H. Maffly will be presented with the Gift of Life Humanitarian Award from the National Kidney Foundation of Northern California on Sept. 13.

The foundation is honoring Maffly, Stanford medical school associate dean for student affairs and professor of nephrology, with a scientific symposium and a testimonial dinner on the same day.

Maffly is receiving the award for "his research in kidney disease, involvement in kidney organizations, improvement of patient care and the training of medical students, housestaff and fellows in kidney disease."

The all-day symposium, "Review of Nephrology," will be held at Fairchild Auditorium, Stanford University Medical Center. The dinner will be held at the Stanford University Faculty Club that evening.

Proceeds of the program will benefit the National Kidney Foundation and the Robert Maffly Endowment Fund for Stanford Medical Students.

Maffly has served in numerous positions since he joined the Stanford medical faculty in 1961. He currently co-heads the division of nephrology in addition to his responsibilities as associate dean for student affairs. He has received eight awards for excellence in teaching, most recently the university-wide Walter J. Gores Award. Maffly is the first medical school faculty member ever to receive the award.

Maffly has been actively involved with the National Kidney Foundation and the American Heart Association in research and leadership capacities. In 1984 he received the AHA Scientific Council's Distinguished Achievement Award.

Maffly has also been a member of the Board of Trustees of the Satellite Dialysis Center, a non-profit corporation that provides dialysis in Northern California and contributes to kidney research.

For more information about the symposium or the dinner, call the national Kidney Foundation of Northern California at (415) 697-0110.

STANFORD HOSPITAL FACING FEWER PATIENTS ADOPTS NEW STRATEGIES

STANFORD—

A slogan floating in the hallways of Stanford University Hospital these days is something called the "paradigm shift."

To those unfamiliar with the term, its mere mention evokes smiles or bewilderment. But to managers, concerned about a shrinking patient census and bottom lines necessary for the survival of the hospital, the idea is nothing more than a strategy shift to meet the trends reshaping medical care.

"The message we're trying to get across is that we must change our primary standard of excellence," said executive vice president and hospital director Sheldon S. King in an interview. "For lack of a better term we've adopted 'paradigm shift,' meaning that we will make the satisfaction of physicians and their patients our first priority.

"If the physicians are unhappy, chances are their patients are unhappy. It comes back to the fact that rarely patients choose hospitals. It's doctors who decide."

This message seems to have been lost in university hospitals, King explained. "Until now their training and research missions were guided by national policies that had allowed them to place their priorities closer to their institutional convenience. This isn't true anymore.

"We are in a period of review and change in America's traditional health care systems. Hospitals must incorporate institutional values, employee concerns and patient considerations into their everyday operations. Patient service, teaching and research and public education must be blended with all factors which influence the productive functioning of the hospital."

To make the point, King cited the hospital's computerized accounting system. "It produces timely bills and the people who use it have done an excellent job," he said. "But the system still produces an unintelligible bill. Our mistake was to build it from the perspective of the hospital, not the patient. Today we'd do it differently."

Stanford hospital will stress more than ever the importance of service in personnel training and hiring, King said. "We now have a plan. It's a draft because it must be flexible, but it identifies some of the directions we'll be taking."

The plan, he said, reflects not only his own but the hospital board's concerns—"how to care for patients in a less costly way, with the quality a hospital such as Stanford should provide."

When he came to Stanford from the University of California at San Diego, King had said, "I believe I do understand what it takes to make a large teaching hospital run effectively. That's what I'm here for, and essentially it is what I am interested in professionally."

In four years, the 54-year-old executive has been recognized for his deft touch in guiding the process of change. He started by telling hospital managers they must look at goals, resources, and budgets and consider needs of the immediate and national communities served by Stanford hospital.

He assembled a new management team, and developed a program in which objectives were specified in writing along with departmental action plans accompanied by timetables for completion and evaluation.

"Interactions between subordinates and supervisors in deciding objectives leads to improved performance," King said.

The result: a hospital which has run consistently in the black.

King attributes the success, in part, to the hospital's reorganization as a university "sister" corporation. "It has allowed us to set priorities, adapt more readily to external challenges, and develop more comfortable relationships with the medical school and the community physicians," he said.

The "sister" corporation status enables the hospital to enter into joint ventures not only with the medical school and the faculty practice, but other organizations, King said. "We're still tied to the mother house, yet independent enough to pursue relationships as a community hospital."

For example, the hospital participates with the Palo Alto Medical Clinic in TakeCare, a prepaid health plan sponsored by Blue Cross, and it is discussing other possible joint ventures. It is a participant in Blue Shield's prudent buyer plans. And it is exploring with a group of independent physicians prospects for offering primary care services to employees of local corporations. Other efforts include the launching of a home care program, and Life Flight, a helicopter emergency service run jointly with Santa Clara Valley Medical Center.

In January, in addition to his present duties, King will become president of the corporation, succeeding Dr. Lawrence G. Crowley, the vice president for medical affairs who recruited him. Crowley will be returning to academic duties.

Clad in a light beige suit and a tie, the confident, tough but congenial King candidly touched on a wide range of topics during the hour-long interview. He included things he found professionally satisfying and those that have frustrated him most. Some excerpts:

On medical education and the teaching hospital—"The metaphor of the three-legged stool—education, research and patient care—often invoked to describe the functions of academic medical centers is no longer valid. It may be a triangle, but the sides are not equal. There's now a longer side—patient services. Within that I would subsume the members of the medical staff and their satisfaction. An emphasis on patient care is not a conflict of values. It's the proper environment for a hospital where young physicians are trained."

On relationships of medical school and hospital—"Dean David Korn and the decisive approach he brings will match what the hospital needs from the medical school side. There will be very good consonance in direction. The school and hospital, for example, have been working closely on joint ventures in magnetic resonance imaging and ambulatory surgery. The hospital is a participant with the faculty practice in Maxicare, one of the nation's largest private health maintenance organizations. These represent a real joining of interest and a sharing of risk-taking which are positive features."

On the decline of patient census—"In a way you may associate the decline with my arrival. But perhaps all that means is that I came at a time when the new era, the re-regulated era in patient care, was beginning.

"We are now faced with a competitive economy. For hospitals it translates as competition on the basis of cost since there's no yardstick for measuring quality in health care.

-more-

"Stanford is perceived as an expensive hospital. It's perhaps one reason why some patients go elsewhere. But comparisons are misleading. When hospitals claim they are providing superior quality of care, they are looking only at morbidity and mortality statistics. These don't tell you what the patient's condition was like when treatment began.

"Community hospitals treat healthier patients without the overlay of teaching. At Stanford we can make a substantial argument that having a housestaff makes our intensive care units more cost-effective.

"Our challenge will be, Can we continue to attract patients to Stanford for particular services? Can we make our focus one which gives physicians good reasons to want to bring their patients? Our hospital modernization will help. It means we'll have new facilities, including enough operating rooms to meet medical staff needs. Many of our very talented physicians do not admit patients now because of the physical limitations. The number of private rooms for patients will be increased. And a new, attractive Children's Hospital linked to a Women's Center, handling not only perinatal medicine and routine obstetrics but all women's illnesses, will give us a unique facility."

On physician relations—"One of my tasks has been to begin a dialogue with our physicians, both on the full-time faculty and the community side. We have had frank and interesting discussions. Rarely are two consecutive meetings the same.

"But I'd like to see an end to the acidity that has characterized relationships in the past. The medical staff should feel more a part of the decision-making process. Physicians participate in the development of the capital budget now and we follow their recommendations. We want them involved in the operating budget, too, which is really a translation of the hospital's objectives. By that I don't mean participatory democracy. It's my responsibility to make decisions, with the kind of information only the medical staff can provide.

"To strengthen the hospital, we must get rid of administrative rigidities. We have physicians in the community who seek access to hospital laboratories as voluntary faculty. The hospital board has policies governing the conditions of access. Many university services are cooperating, but others seem unable to act quickly to implement board policy. Meanwhile, we are confronted with an underutilized hospital. While we agree the primacy of our university hospital is important, to maintain it by sacrificing its community component would be unrealistic. The result would be a 200-bed hospital, which would suffice for nothing."

On the board of hospital directors—"The separation of the hospital allowed the creation of an exceptional board. We're very fortunate, and I am saying this because I really believe it. Our board members are helping to shape and provide direction for the hospital, which is much more tuned to the times."

On the need to be proactive—"We have not moved quickly enough to seize initiatives. Our pace of change, our ability to respond to external factors is still slow. I understand the reasons since I have worked in academic institutions all my life. But it represents a clear and present danger no longer acceptable. If we continue to move deliberately and slowly, too much will have passed us by.

"It has to be part of our understanding that we can make mistakes, that most of them are retrievable and there's nothing wrong if something didn't work no matter how carefully we planned it. We have to make decisions and move when we have enough facts to do so, not when we have *all* the facts. In an academic environment one wants to have as many facts as he can get. But I don't think in today's competitive environment it's a plausible approach."

On the challenges facing the hospital—"These are not exclusively Stanford's. They affect all hospitals. One can look at what is happening to the proprietary health care corporations. They were touted as the prototypes of survival for health care in the eighties and nineties, but they've run into considerable difficulty. Their expansionist philosophy began to backfire as the health system entered a period of retrenchment and consolidation.

"Stanford faces problems that are national in scope—how to pay for graduate medical education, how much graduate medical education there should be in light of a predicted glut of physicians. We'll have to look at the size of our housestaff, but only in terms of the size of the population treated at Stanford hospital. Unless we introduce new services to justify its size, there will be a need to do something about. But I wouldn't relate such an action to the national issue of physician surplus.

"If one wanted to reduce the number of residencies in this country, he should start with those that are third-rate. They are not here at Stanford, which is not to say the each of ours is supurb either. But they can be strengthened."

On his administration—"It did take us awhile to build up momentum here. Part of the reason was changing the team, part was being able to understand the complexity that is Stanford hospital, and learning how to move it. I don't think we've done it yet completely, but we've learned how to do it.

"Next year when I reach five years on the post, I expect to ask the president of the university for a formal review. This is not only to decide whether we have taken the right course, but also to determine future directions. It's my responsibility to make sure it happens. The evaluation should not be done by the hospital board alone, but the medical staff, including people who disagree with me."

On his vision about Stanford hospital—"I see Stanford hospital as having a unique responsibility. It comes with its being one of a dozen institutions the country cannot do without, because they're essential to our national purpose and to the progress of medicine. My goal is to make certain that this hospital emerges as a leader in that group—in the development of new delivery patterns, applications of new technology, and as a model institution."

DIABETES STUDIES NEED VOLUNTEERS

STANFORD—

Volunteers in general good health are needed for three studies being conducted at Stanford University Medical Center by Dr. Gerald Reaven, professor of medicine, and his associates.

In one study individuals with diabetes as well as non-diabetic volunteers will participate in a study to help determine if fat cells of individuals with diabetes mellitus respond differently to insulin than fat cells from individuals without diabetes.

Volunteers should be between 20 and 75 years old and able to spend two to three days over a two week period in the Clinical Research Center (CRC) at Stanford University.

Another study will test individuals with diabetes with a newly approved oral medication for diabetes.

Volunteers for the second study should be between 20 and 65 years old and be willing to switch to the new drug from their current medication. They should be able to spend three to five days in the CRC to adjust to the new medication. Participants will then be monitored on a weekly basis for three months.

Individuals with diabetes are also needed in a third study to determine whether the addition of an oral agent to individuals with diabetes who are poorly controlled on insulin alone will improve their diabetic control.

These volunteers should be between 35 and 65 years old, currently taking 40 or more units of U-100 long acting insulin (NPH, Lente, or Ultra Lente), and be able to spend one to three days over a two-week period in the CRC.

Volunteers will receive free a complete medical examination including blood chemistry and urinalysis, an EKG, and dietary consultation.

For more information, contact Dr. Claire Hollenbeck or Dr. Arthur Swislocki at 497-6973, between 9 a.m. and 5 p.m.

FORMER TIMES-TRIBUNE EDITOR NAMED TO STANFORD NEWS POST

STANFORD—

Two appointments to fill personnel vacancies, and a change in staff responsibilities at Stanford University Medical Center's Office of Communications were announced Thursday, Oct. 31, by Spyros Andreopoulos, director.

Ron Goben is the new associate director, and Jane Ayers Reimold is publications editor.

News editor Mike Goodkind now becomes the new editor of the *Medical Center Report*, a weekly supplement of Campus Report. He will continue to edit *Medical Staff Update*, the publication of the medical staff, and will be responsible for *Health Tips*, a new feature service scheduled to start this fall.

Laura Hofstadter remains science editor, and Shirley Kraus will continue as managing editor of *Stanford Medicine*, the medical center's magazine.

Goben, veteran journalist, former city editor and associate editor of the editorial page of *The Peninsula Times Tribune*, will report on scientific, medical and administrative developments at the medical center and hospital, and will participate in the day-to-day management of the office, Andreopoulos said.

Reimold, former manager of the communications division of the American College of Physicians (ACP) in Philadelphia, will be responsible for writing, editorial supervision and production of informational publications of the School of Medicine and Stanford University Clinic, in addition to reporting.

A graduate of Northwestern University's Medill School of Journalism, Goben worked as an editor for the *Chicago Tribune* and *Honolulu Star-Bulletin*. He covered medicine from 1964 to 1969 for the *Palo Alto Times* before the paper changed name and ownership. He has authored a medical book and has contributed popular articles on science and medicine to national magazines.

Reimold received a degree in journalism from Ohio University, Athens. She worked as a reporter/researcher for *Forbes* magazine, and from 1980 through the present helped to create and manage the communications program of the ACP.

The realignment of responsibilities was occasioned by the recent departures of staff writers, Lisa Ames and Jacki King, said Andreopoulos.

CLUES ON NERVE CELL GROWTH AND FUNCTION MAY LEAD TO NEW TREATMENTS FOR CRIPPLING CONDITIONS

STANFORD—

Late one May evening in 1978, an elderly north Bay Area man and his wife were shot through their locked front door in an attempted robbery. Mr. Niemela, an 83-year-old retired San Francisco businessman, was killed instantly. His 79-year-old wife, Isabelle, was paralyzed from the neck down by several bullets that lodged in her spinal cord.

In the aftermath of the tragic event, Mrs. Niemela spent six months convalescing in the specialized spinal cord injury unit at Santa Clara Valley Medical Center, where she was surrounded by other paraplegic and quadriplegic patients. Their plight deeply distressed the elderly widow. When she died in 1981, she left more than two million dollars, one million of which went to Stanford University, to support basic biological research that could lead to a paralysis treatment.

Mrs. Niemela's bequest, part of which supports research at Stanford Medical School, may offer hope to the approximately 10,000 people who suffer spinal cord injuries each year in the United States. Because cells in the central nervous system do not regrow after damage or injury, the condition is irreversible. Until now, medicine has had little to offer.

But scientists are beginning to make headway against nerve injuries. With the new tools of molecular and structural biology, they are looking inside nerve cells to discover how they function and grow. The findings could lead to new approaches for treating paralysis, as well as to treatments for crippling conditons such as stroke, multiple sclerosis and degenerative nerve diseases like amyotrophic lateral sclerosis, better known as Lou Gehrig's disease.

Stanford scientists are exploring different approaches to reversing nerve cell damage. One is regeneration, the regrowth of severed, crushed or otherwise broken nerves. Another is reviving lost function in sick or degenerating nerve cells.

"Functional recovery is really what we want, whether it's restoring function in a damaged nerve fiber or regrowing a physically severed one," says Dr. Stephen Waxman, Stanford neurology professor and head of the neurology service at Palo Alto's Veterans Administration Medical Center. "You don't have to spend much time on a neurology or spinal cord injury ward to know that if we could repair just five percent of the lost nerve fibers, these patients would put them to use."

Getting nerves to grow seems like it should be a straightforward task. Skin grows back after it's cut, so why not nerves? A first step toward answering that question is to study nerves at the one time in life that they do grow: development.

The nervous system takes form as millions of newly born nerve cells, or neurons, sprout long fibers that elongate and connect up with target organs or other nerve cells. Each neuron knows just which other neuron to connect with. Like millions of elongating tentacles, the fibers, called axons, grow purposefully to their targets. But once the axons reach the target cells, growth stops.

In some cases, growth can recur. For example, peripheral nerves—the network of nerve fibers that reaches out to muscles, skin and other parts of the body—may regrow after being severed or crushed. Central nerves in some lower animals, such as fish and amphibians, can regenerate following injury. But in humans and other higher animals, neurons in the brain and spinal cord, called the central nervous system (CNS), do not regenerate, even after injury. Like adult teeth, they grow into place, but once they're lost, they're gone forever.

Or are they? What if scientists could find the "switch" that turns on nerve growth during development? Would it then be possible to flip the switch on and off as needed, triggering axon regeneration after a spinal cord injury, for example?

Stanford neurobiologists are looking for switch candidates among the genes and molecules active in developing and regenerating nerve cells. Dr. Eric Shooter, neurobiology department chairman, is studying one interesting contender, a protein linked to regrowth of damaged peripheral nerves in rats.

The protein, discovered by Shooter and neurobiology assistant professor Dr. Pate Skene, is synthesized at a high rate in young animals while developing nerves are still growing. In adult rats with established nervous systems, the protein is synthesized at a much lower rate. If an adult rat's nerves are damaged, regeneration occurs only in its peripheral nerves. Yet the scientists observed heavy synthesis of the protein in both central and peripheral nerves.

A closer look showed that the protein accumulated in peripheral nerves but didn't collect around central nerves. Stockpiling of the protein in peripheral nerves may contribute to their ability to grow, the scientists believe.

Skene and Shooter and their colleagues have now found that the protein is almost identical to a blood protein that shuttles fats in and out of cells in the body. Their suggested role for the protein, which is supported by preliminary evidence, is that it helps sponge up fat molecules that spill out of the damaged nerve cells. Then it hangs around with its fat cargo, which can be reutilized in construction of the new nerve that grows through.

While they are investigating further this protein's crucial role in peripheral nerve regeneration, Skene is also concentrating his current efforts on a protein called GAP-43. "GAP" stands for growth-associated protein and "43" stands for the protein's molecular weight.

GAP-43 has been found in growing nerves of animals ranging from goldfish to toads to rabbits. Skene, and his colleague Mark Willard at Washington University, discovered it initially in toads, where it is present in large quantities in the growth cone, the growing tip of regenerating axons.

In mammals—baby rabbits, for example—Willard and Skene found GAP-43 in developing nerves. Skene and Kate Kalil, a colleague at the University of Wisconsin, have found GAP-43 in newly developing axons of baby hamster cells. But as the proper nerve connections form in the maturing baby hamsters, levels of GAP-43 drop off. Skene and other colleagues found a similar pattern in studies of developing rat brain, suggesting that in mammals GAP-43 plays an important part in nerve growth during CNS development.

Are these proteins the crucial switches? "We don't yet know the functions of GAP-43 or other growth-associated proteins," Skene says. "There are a lot of jobs that go into constructing a nerve cell. We need to find out if we are dealing with the scavengers, architects, electricians or plumbers."

Ultimately, the scientists expect that at least several proteins will be needed for successful switching on of nerve growth. Skene has already identified several GAPs other than GAP-43. They hope to find a way of manipulating genes that control these proteins so that they can summon all the necessary "workmen" when nerve reconstruction is needed.

In a slightly different approach to studying nerve regeneration, neurologist Waxman and his colleagues are trying to learn from a master of the trade: the South American electric fish, *Sternarchus*, also known as the black ghost knife fish. This freshwater cave-dweller can regenerate a bitten-off tail, including its spinal cord nerves, within a few months after a predator's attack.

-more-

"What we basically want to find out is what makes the fish able to regenerate so completely when a mammal cannot," explains Dr. Marilyn Anderson, a research associate who works with Waxman at the Palo Alto VA Medical Center. "And is there anything in those mechanisms that we can apply to humans?"

Waxman and Anderson have found that the fish can grow whole new nerve cells, not just new axons, in its spinal cord. Anderson has been able to remove nerve cells from the fish's spinal cord and get them to grow in the test tube. Waxman's lab is very unusual in having the ability to produce new neurons from adult tissue in culture. "The important point is that this enables us to look for the molecular mechanisms that control cell division and differentiation into neurons," Waxman says.

The new nerve cells grow from a region in the fish's spinal cord called the ependymal layer. A similar layer in mammalian embryos gives rise to CNS neurons. But although in the adult black ghost knife fish the layer can spawn new nerve cells, in the mammal it is dormant after the animal is born. But Anderson thinks that the ependymal layer has developmental potential which is repressed in adult mammals.

"If we can find a way to stimulate it—with a hormone, chemical, or other means that we may find in studies with *Sternarchus*—then it may be possible to produce new nerve cells in mammals, too," she explains.

Learning how to produce new or regenerated nerve cells is the ultimate challenge, Waxman says, but the far less dramatic rehabilitation of damaged nerve fibers may be equally useful.

"The word 'regeneration' is suddenly very popular. It connotes regrowth of structure, which is great when it occurs, but you can also get functional recovery from reorganization at the molecular level, as well as from regrowth of the cell at the tissue level," he explains.

"When a multiple sclerosis patient has a remission, he is not regenerating tissue; when a stroke patient improves, he hasn't regenerated neurons. What we want to understand is functional recovery," he stresses.

One of Waxman's main interests is multiple sclerosis, a disease estimated to afflict 250,000 people in the United States. In MS patients, a protein called myelin is destroyed. Like the rubber coating around an electrical wire, myelin is an insulating material that sheathes cells in the CNS. Without myelin, electrical impulses do not travel down the nerve cell membrane and communication along nerve pathways shuts down, which results in weakness, paralysis, tremors and disturbances of speech and vision.

MS can be like a teeter-totter, Waxman says. "Patients may get better, then worse, then better again," he explains. "There are very few neurological diseases that do this. We desperately want to understand the molecular basis for this apparently spontaneous recovery."

Waxman and colleague Joel Black think they have found a clue from examining the structure of tiny channels through nerve cell membranes that are responsible for impulse conduction. Sodium channels are protein molecules that function like molecular "batteries" in promoting impulse conduction in nerve fibers; potassium channels make neurons more resistant to firing. The sodium channels are clustered at gaps in the myelin, forcing impulses to jump between gaps, like arcing sparks.

When myelin insulation is destroyed in MS, impulse conduction is blocked because underneath the myelin there are no sodium channels, just potassium channels. The membrane is "essentially electrically dead," Waxman explains.

So why do MS patients experience remissions? Waxman, Black and their colleagues discovered that following demyelination, sodium channels may begin to pop up in the demyelinated regions, allowing impulse transmission to resume. Although this migration of sodium channels into demyelinated regions may not be the total explanation for remission in MS, it is probably an important factor, Waxman believes.

The scientists therefore are eager to understand how it occurs so that perhaps they can hasten the process to help alleviate MS symptoms. "We don't have a cure in our front pockets," Waxman cautions. "But we are beginning to understand what's going on, and that is very exciting."

more

4-4-4 Neurologist Dr. Jeffery Kocsis, one of Waxman's colleagues, is also trying to find ways of overcoming conduction block in MS.

"We are trying to understand the basic biology, the organization of channels in the nerve cell," he says. "Then we can look for ways to improve conduction through the blocked sites."

Even if scientists some day find a way to prevent MS, Kocsis explains, therapy will still be needed for those who already have the disease and for patients whose disease is too far advanced to turn around. "Our ultimate goal is to manipulate malfunctioning nerve fibers that are still intact," he adds.

In studying membrane channels, Kocsis and colleagues use some promising new experimental drugs that block potassium channels. One drug is already undergoing tests in Europe in patients with neuromuscular disease.

Kocsis believes that scientists need a better understanding of the drug—called 4-amino pyridine—at the physiological and molecular levels. He is studying the drug's effects in rats afflicted with a disease that resembles MS. By blocking the inhibitory potassium channels, the drug helps boost nerve impulses across the electrical wasteland of demyelinated nerve membrane.

It is important to know the drug's effects on all nerve activity, not just on demyelinated fibers, Kocsis says. For example, one side effect patients experience is an unpleasant tingling sensation. Kocsis has found a physiological explanation for this phenomenon. The drug produces bursts of impulses in sensory fibers—the nerves that carry sensory information into the brain. Lowering the drug dosage helps curb the effect.

In other studies of potassium blockers, Kocsis and Waxman discovered that regenerated peripheral nerves in rats are structurally different from the original nerves they replaced. The regrown nerves seem good as new—from observing how well the animal functions—but unlike newborn nerves, they are sensitive to potassium blockers. The scientists found out why: Little pieces of myelin continually fall off and get replaced in regenerated nerves.

"So although functional recovery occurs, sensitivity to pharmacological agents can be vastly different in original and regenerated tissue," Kocsis observes.

"Drugs can always be double-edged swords," adds Waxman. "We need to proceed slowly and carefully in considering them for any kind of therapy."

Ironically, sometimes nerve regeneration, one of medicine's long-sought goals, can be bad. For example, if a cut arm is surgically repaired, regrowing axons may get lost on their way back to the original targets. The fibers twist and gnarl to form a knot called a neuroma, Kocsis says.

"It's a major clinical problem that is excruciating for patients because it becomes abnormally sensitive to touch and to some chemicals." Current treatment—involving surgical removal and then hope that the nerves will grow back in a less contorted fashion—is not very effective, Kocsis adds.

In neuromas removed from rats, Kocsis has found that the extreme sensitivity arises from electrical "crosstalk" between nerve fibers.

"Normal nerve fibers are spatially separated from each other," he explains, "but neuromas are made of very thin sprouting fibers and the electrical activity in one can activate the other axons around it." The result is an avalanche of electrical activity that the patient feels as intense pain.

Kocsis and his colleagues are now looking for abnormalities in membrane channels or in membrane receptor proteins that may be involved in the increased excitability. These could then become targets for drug therapy to shut the fibers off.

Nerve regeneration—for better or worse—still remains largely out of medicine's reach. But researchers who believe it may be the only solution for certain medical problems are convinced the remaining obstacles eventually will be overcome. "Some research focuses on the biochemical 'soup,' and some on nerve 'sparks,'" says Waxman. But the common goal—to understand nerve function and growth—should bring the day closer when broken nerves can mend. "It may seem like fantasy right now," says Kocsis, "but let's see what happens in the next couple of decades."

EDUCATION, LEGISLATION WILL CONQUER HEART DISEASE, SAYS STANFORD EXPERT

STANFORD—

Heart disease is beginning to yield to public awareness of how to avoid it, as well as to better treatment, yet a Stanford expert says tough legislation to deter smoking is needed to topple the reign of the nation's number one killer.

Statistics prove lifestyle has a major impact on heart disease, said Dr. C. Barr Taylor, director of behavioral science for the Stanford Center for Research in Disease Prevention, in a talk Thursday night (Oct. 24). And he gave an encouraging account of a Stanford study that has used social learning theory to inform and persuade Californians to adopt healthier living habits.

Preliminary results show the percent of smokers in populations targeted by the Stanford study has been cut in half, he reported.

But, he said, it will be harder to convince the remaining half to quit.

Taylor, who is associate professor of psychiatry at Stanford, warned that our society is beginning to split along a line dividing those who have access to health information and have changed their habits, from those who do not and have not.

"We run the risk of creating a class structure based on health," he said.

Recognizing that smoking is "highly addictive and strongly perpetuated in our culture," he called for a ban on all cigarette ads, an end to tobacco subsidies, and higher excise taxes to deter smokers, in order to achieve the Surgeon General's goal for a smoke-free society by the year 2000.

Half of the decline in deaths from all cardiovascular diseases in the United States that has occurred in the last two decades has come from changes in lifestyles, Taylor said.

He estimates that the fall in smoking accounts for 24 percent and decreased cholesterol consumption for 30 percent, while bypass surgery is responsible for only 4 percent (the remainder is due to other medical treatments).

Other preventive methods that are conquering heart disease relate to food. Chicken is beginning to replace beef as the mainstay of the American diet, he said, and egg consumption has nose dived since the 1950s.

This change in eating habits "is reflected in a corresponding (downward) shift in mean cholesterol levels" in the blood of Americans of all ages, Taylor said.

Another chart he presented illustrated that Americans now are better informed about risk factors than the British, and the U.S. death rate from cardiovascular disease has dropped below theirs.

Early findings from Stanford's Five Cities study reinforce this impression that knowledge leads to health. The test subjects in several small California cities (population of about 100,000) who were given a media blizzard of health tips are smoking less, have lower blood pressures, and have gained less weight with age, compared to matched residents of other, similar sized cities in the state who received no health instruction, Taylor said.

He projected that the Stanford study had achieved "close to a 20 percent smoking rate" in Salinas, a test city, as compared to a rate of 30 to 40 percent in many other American communities.

The project, headed by Dr. John Farquhar of Stanford, is now in its sixth and final year of educating, he said, but a complete analysis of the results will not be available until next summer. Moreover, he added, all of the tangible benefits to the participants' life spans may not be apparent for another 20 or 30 years.

In his talk at Fairchild auditorium, sponsored by the Friends of Psychiatry and Behavioral Sciences, Taylor showed the audience some of the 30 second TV spots that were aired in the test cities of Monterey, Salinas and Pacific Grove. The TV commericals featured interviews in which people who have given up cigarettes tell how they succeeded.

"We provide a model for social skills," Taylor explained, "we don't try to frighten people" into quitting.

The multi-million dollar research project also ran stop smoking contests, and stuffed 3 million "hints on heart healthy food" leaflets into grocery bags. More tip sheets on nutrition were mailed, accompanied by a Stanford logo magnet for pinning the flyers to the family refrigerator, Taylor said.

Accompanying fact "kits" on exercise stressed walking, "which is much more compatible with most people's lifestyle," he said, adding, "we wanted to get away from the 'no pain no gain' philosophy."

The health campaign was also conducted in Spanish, with the motto "Yo no fumo," Taylor said.

Outreach to the Spanish-speaking residents in the test cities was important, he said, as cigarette smoking rates have been rising among migrant workers.

"We need to continue disseminating the information (on heart risks) that has become common in our society, but has not yet moved into many socioeconomic groups," he said.

In general, he pointed out, blue collar workers persist in smoking, but that the stratification of healthy habits is not strictly by economic class. For example, he said, many nurses are still smokers, while most doctors have stopped.

Improved medical treatments to help those who already have cardiovascular risks are also needed, Taylor said.

Medicines to cut cholesterol levels are "literally difficult to swallow," he pointed out, referring to the unpalatable resin, called cholestyramine, that doctors prescribe to bind cholesterol in the gut and keep it out of circulation.

"What we need," he joked, "is a drug that could neutralize even the creamiest French meal before it could hit our bloodstreams."

STANFORD CLINIC LAUNCHES IN VITRO FERTILIZATION PROGRAM

STANFORD—

An in vitro fertilization program has been started at Stanford University Clinic, involving an initial group of five couples who have been unable to have children.

The program is headed by Dr. Emmet J. Lamb, director of the reproductive endocrinology and infertility service of Stanford's Department of Gynecology and Obstetrics. He said formal planning for the program started in May of 1983, but "in 1978, we knew we were going to be doing this." He was referring to the birth in England that year of Louise Brown, the first so-called "test-tube" baby.

"We made the decision at that time," Lamb said, "that we would wait until this was clinically useful and no longer strictly a research procedure."

Since 1978, there have been more than 1,000 IVF births worldwide and there are more than 100 IVF programs in the United States, including programs at the University of California-San Francisco and Alta Bates Hospital in Berkeley. Lamb regards both programs highly and has referred patients to both.

All of the IVF programs are expensive and Stanford's is no exception. It will cost $5,000 for each cycle of treatment. And only 10 percent of the couples who start each cycle can expect to have a baby at the end of the process.

However, that 10 percent compares very favorably with the 2 percent monthly pregnancy rate that can be expected by the average infertile woman, such as those registered in the Stanford infertility program. In addition, there are some women for whom in vitro fertilization offers the only hope of pregnancy—those with no fallopian tubes or tubes that are so severely damaged an egg cannot pass through from the ovaries and be fertilized.

Basically, the IVF process takes care of that by having fertilization in a plastic dish instead of the fallopian tubes. Eggs are removed from the ovaries, fertilized with sperm from the husband and inserted in the uterus with the hope that a healthy baby will result.

The actual process, of course, is vastly more complicated than that and it involves an elaborate array of equipment and testing procedures.

For a woman admitted to the Stanford program, the process begins with the start of her period, day one of the cycle. Two days later, she begins taking drugs to enhance ovulation. It is hoped that will stimulate the production of more than one follicle containing an egg; the more eggs that are available, the greater the chance of IVF success.

On the eighth day of the cycle, physicians begin ultrasound examination of the ovaries to check on the number and size of the egg-bearing follicles. When it is determined the follicles are ready, the patient receives an injection to trigger ovulation.

About 36 hours later, doctors perform an operation called a laparoscopy to "harvest" the eggs. A special telescope is inserted through the belly button to view the uterus, tubes and ovaries. Then a needle is inserted into each follicle and suctions out the fluid containing the egg. This operation at Stanford will usually be performed under local anesthesia.

The next step takes place in the laboratory. A gamete biologist examines the follicular fluid under a microscope for eggs. Any eggs are transferred to culture dishes containing a nutrient and placed in an incubator.

In the meantime, the husband has produced a sample of semen, and active sperm cells have been collected in a test tube.

About six hours after laparoscopy the biologist determines if any eggs are mature and adds sperm to any dishes containing mature eggs. If an egg does not appear to be mature, the biologist waits 24 hours before adding sperm.

That is the in vitro fertilization process. If it works, one or more of the eggs will have developed into embryos of 2 to 16 cells in two or three days. At that point, the eggs are placed in a catheter and transferred into the uterus through the cervix. That operation is usually simple and painless, requiring no anesthetic.

Now it's up to nature. If one or more of the embryos is successfully implanted, blood tests in about a week will show the woman is pregnant.

Obviously, there is a lot that can go wrong in such a complicated process. The Stanford IVF team took great care to point out the pitfalls to about 20 people attending an introductory session this month.

Team members went over the expected rates of success for each step in the process and explained that refunds would be available if there were failures at certain steps. For example, participants will be refunded $3,800 of their $5,000 if they do not go through laparoscopy because of a lack of harvestable eggs.

In addition, the doctors told prospective patients to consider the possibilities of multiple pregnancies and complications from laparoscopy, even though the likelihood of such problems is rare.

Lamb said the Stanford team's emphasis on the problems that can be expected in the program is "deliberate and it is designed to offset the wild enthusiasm other people have expressed. These are people who have a chronic disease and people with chronic diseases, whether it's cancer or arthritis or what have you, look for the magic cure. This is an extremely useful and wonderful technique, but it's not the magic cure for everybody."

On the other hand, it may be a magic cure for some women who have no hope of giving birth through other means. And Lamb sees the possibility of higher success rates in the future through the development of techniques to freeze eggs that could then be implanted in a woman's uterus during her next cycle.

He also thinks it's possible that advances in technology will make the IVF process simpler and therefore less costly.

But for the present, it's expensive because of the initial cost of elaborate equipment and because the process is "labor intensive," Lamb explained. That cost to Stanford is at this point considerably higher than the $5,000 charge for the treatment and makes it necessary, Lamb said, to have "a certain number of patients above the minimum required for our teaching goal."

However, he emphasized, IVF "is just one of the treatments that we use for infertility and we don't want to get into a situation where we are running just an in vitro fertilization clinic."

The members of the Stanford IVF team, in addition to Lamb, are Dr. Frank F. Polansky, a specialist in reproductive endrocrinology and infertility; Dr. Amin Milki, a fellow in reproductive endrocrinology and infertility; Dr. Tsai-feng Wu, laboratory manager; Eve Shen, gamete biologist; and Kathy Turner, nurse coordinator. Jill Field, a social worker in Palo Alto, will work with participants in the program to help them deal with psychological problems.

PSORIASIS SUFFERERS SOUGHT FOR RESEARCH STUDY

STANFORD—

The Department of Dermatology at Stanford Medical Center is seeking psoriasis sufferers in general good health and more than 18 years old to test an experimental drug.

Diane Wenner, coordinator of the study, said volunteers will be given without charge a complete physical examination, chest X-ray, EKG and blood chemistry screening.

About six serious sufferers of the skin malady will ultimately be accepted for the study starting Oct. 28 and will visit the department daily Monday through Friday for four weeks to have the drug injected.

Each daily visit to the Medical Center will last about 15 minutes and any patient who completes the study will receive $150 reimbursement, Wenner said.

The study is part of a continuing evaluation of a new drug, Wenner said, and volunteers will be given further details about its treatment potential.

Persons interested in volunteeering should contact Wenner at (415) 497-7964.

PHYSICAL, ORGANIZATIONAL CHANGES IN PLACE AT STANFORD CLINIC

STANFORD—

A medical historian attempting to chronicle the dramatic changes taking place in American health care could get a good idea of the situation simply by examining what is happening at the Stanford University Clinic.

The changes at the clinic reflect those occurring throughout the medical world and are the result of the same pressures of economic necessity and competition for patients.

In the past few years, the clinic has shifted its emphasis from specialization to a full range of patient care services and made a concerted effort to change its image from that of a sort of silent partner to the internationally acclaimed teaching and research arms of the medical center.

That new emphasis combined with the specialized expertise available through the medical center gives the clinic a medical care package that is "very, very attractive and probably one of the best in the world," according to Donald B. Tower, executive director of the clinic and the Faculty Practice Program.

"We're always on the cutting edge of medical treatment," he said. "We apply the techniques that result from our research to our patients and so our patients wind up getting state of the art in terms of medical care."

The clinic returns that kind of assistance to the other components of the medical center by providing a strong clinical practice, said Dr. David Spiegel, an associate professor of psychiatry and chairman of the clinic's professional practice committee.

"Excellence in one area facilitates excellence in another," he said. "Having a clinical program that attracts the best physicians can only enhance the mission of the Medical School."

The clinic is 26 years old. It was established in its present location in 1959, when the School of Medicine moved to the Stanford campus from San Francisco. Patient visits have grown from 20,000 in 1960 to more than 142,000 last year and there are now 280 physicians on the staff.

That growth made it apparent a few years ago that a major expansion of facilities was needed. The first two floors of the Boswell Building, housing the clinic, have been renovated and work on the third floor is under way. The $6.5 million project was financed largely by a gift from the James Boswell Foundation, the contributor to the original building.

According to Tower, the renovation has not only made the operation of the clinic more efficient, it has made it more attractive and pleasant—"a nice place for patients."

Just as important as the physical atmosphere from the patient point of view is the availability of primary care, which began in 1981 with the establishment of the Stanford Medical Group.

The SMG was started in response to patients' expressed desires to have a Stanford clinic doctor as a personal primary care physician. It now has five internists, all of whom are members of the Medical School faculty. Dr. Scott Wood, one of the group, said the physicians spend 70-80 percent of their time in primary care, seeing patients just as they would in private practice. The remainder of the time is spent teaching.

A little more than a year after the start of primary practice, there was a more subtle change that indicated the direction of the overall practice: The name was changed from Stanford University Clinics to Stanford University Clinic. Dropping that "s" signifies that the semi-autonomous clinics of the past are gone and "we are one unified group," according to Vera Waechter.

Waechter, assistant director of the Faculty Practice Program and director of clinic nursing, pointed out that there is physical as well as organizational unity.

"All of our ancillary facilities are in the same building," she said. "If a patient needs to have blood drawn and an X-ray examination, they're all in the same building."

That proximity is part of an exceptional emphasis on patient convenience and comfort that Waechter said is built into the new clinic facilities. Among other examples she cited:

- Large, pleasant examination rooms that are at least 120 square feet and provide space for family members as well as consulting physicians.
- Spacious waiting rooms designed with the aim of making waiting as comfortable and relaxing as possible. The waiting rooms have music and are situated away from the areas of heavy traffic.
- A specimen collection area and pharmacy conveniently placed near each other in the main clinic building.
- Waiting rooms and examination rooms painted in colors selected for their soothing, cheerful effects, and decorated with copies of well-known art works.
- Lights outside each examination room that flash on when they are in use.
- Rugs coded by color for each different clinical area, making it easier for patients to be sure they're in the right part of the building.

Outside the clinic, there's the same emphasis on patient comfort and convenience, Waechter said, noting that 300 parking spaces have been set aside for patient use. Referring to the frequent traffic problems around the medical center, she said, "We don't want patients to have to hunt for parking. Sometimes doctors can't find parking, but patients can."

All the attention to detail has paid off, according to nurse-manager Carol Hendrickson, who said patients frequently comment "on the art work and the cheerfulness of the place...It's just a nice place to walk into."

Dr. Keith Taylor, chairman of the clinic marketing committee and director of medical specialties, agrees that "patient satisfaction has enormously improved," but he is equally pleased with the way the changes have improved working conditions and efficiency.

"It's a much better means of handling the patient load," he said. "Central desks can coordinate services much more efficiently."

The physical changes have been particularly impressive to Dr. Robert A. Chase, professor of anatomy who was among those who moved from San Francisco to the Stanford campus in 1959.

He remembers that the space was adequate at first because of a relatively low patient load, but was quickly outgrown. His special pleasure in the new clinic is the size of the examination rooms; the old ones were "very, very inadequate."

But one thing that hasn't changed is something in which Chase takes great pride: the clinic's array of medical experts. "We're able to locate super experts in any domain," he said. "Each time a new field develops, we seem to have an expert."

To take full advantage of that expertise, the clinic is reorganizing its administrative structure as well as altering the physical environment. Spiegel is heavily involved in that reorganization as chairman of the professional practice committee and he sees efficient operation as crucial to the long-range success of the clinic in a highly competitive situation.

The reorganization involves a separate administrative structure to give clinic chiefs more responsibility and it includes changes in subcommittees operating under the professional practice committee, which is essentially the line governing body of the clinic. The subcommittees now include one dealing with the allocation of space, one handling credentials, one reviewing patient care and one dealing with quality assurance.

Spiegel hopes the reorganization will position the clinic to aggressively seek patients, which he sees as essential because of the increasing competition in the health care field and the changing role of the government.

He notes that many current patients seek out treatment at Stanford—"more than half of the clinic referrals are self-referrals"—but fears that patients in the future will have limited options in selecting treatment.

"We estimate in eight to ten years virtually all patients will be tied up in plans that restrict freedom of choice," he said. "If we do not get involved (in such plans), we will lose half of our patients."

The clinic has taken one major step toward such involvement by signing an agreement to provide medical services to the subscribers of Maxicare, one of the largest health maintenance organizations in the country.

Too much government influence in health care is another problem that must be dealt with in the future, Spiegel said. He called changes in government financing of health care "a particular threat to teaching clinics as well as hospitals." He also warned about a future in which "institutionalized health care will result in doctors being evaluated solely for their productivity."

"Increasingly now it's systems treating people," Spiegel said. "We try to preserve at Stanford the notion of individual responsibility. That's a crucial part of the medical tradition."

Stanford, he said, must continue to fight for that notion of individual responsibility—in the clinic, the hospital and the medical school. "If we don't do it, how do you expect others to?" he said. "People notice what we do. We have a special responsibility to set an example."

WHAT MEDICINE CAN DO ABOUT PAIN

STANFORD—

New insight into how the nervous system works has brought an expanding array of treatments to chronic pain, yet even today's most high-tech methods may fail to banish a burden of misery.

But the load can be lightened, according to Dr. Lorne Eltherington, anesthesiologist and director of Stanford University Clinic's pain service.

The service combines nerve blocks and non-narcotic drugs with mild exercise, stress management, biofeedback training, and other positive steps to propel a patient back into an active life.

"We try to convince (pain patients) that they've got to go on with their lives in spite of their pain," Eltherington said.

Those whose search for help brings them to Stanford learn to become participants in therapy, rather than recipients.

"They come in and say, 'fix me,' and we say, 'you've got to fix yourself, and we're going to give you the ideas and treatments to hopefully get you there,'" explained physical therapist Joan Smithline.

The pain service brings together Stanford professionals from the departments of anesthesiology, medicine, physical therapy, and psychiatry, who devise a coordinated approach to each patient's pain.

Therapists at Stanford University Hospital's physical and occupational therapy outpatient services (located at Lytton Gardens in Palo Alto) try to get a total picture of the pain, so they can plan a realistic course of rehabilitation, Smithline said. They start by asking what daily activities make a person's pain better or worse, and look for changes in the bones and muscles that might be contributing to the problem.

And Stanford staff psychologists in the department of psychiatry's behavioral medicine clinic use interviews, questionnaires, and physiological measurements to see if stress or depression is compounding pain. By detailing how an individual has reacted to chronic pain, they can then devise a treatment strategy that is tailor-made to each person.

Many chronic pain conditions bring people to the pain service.

Back pain is most common, accounting for about half of his patients, said Eltherington, who is associate professor of anesthesiology at Stanford.

He estimated that $6 billion is lost annually in this country to medical care and sick leave for people with bad backs.

A third of his remaining cases have myofacial pain, an ailment where touching one area triggers severe pain in another part of the body. Typically, pressure on the upper back in these patients "makes pain go up into the shoulder and neck," Eltherington said. "It can progress to where they can't use their arm," he said.

Current medical knowledge cannot explain why the nervous system plays such cruel tricks in myofacial victims, Eltherington said, and the disorder remains difficult to treat.

more

But he has a better handle on other pain disorders, such as reflex sympathetic dystrophy (referred to as causalgia by the Civil War doctors who first noted the condition), where an injury to the main nerve of the arm or leg leads to hypersensitivity—"you just touch their skin (on the affected limb) and they scream," Eltherington said.

If treated early after the initial injury, reflex sympathetic dystrophy, which affects about 10 percent of his patients, is a "curable chronic pain problem," he said.

Another disorder, though less amenable to therapy, is at least somewhat understood.

Post-herpetic neuralgia begins when the herpes zoster virus that gave a person chicken pox as a child resurfaces from the nerves where it had laid dormant for years. Trauma or cancer later in life rouses the virus into an attack of big blisters that can cover the trunk from mid-back to mid-belly.

The rash, called shingles, fades, but in 15 percent of his patients, pain has remained. It "stabs like an ice pick on top of a constant, unbearable ache," Eltherington said. It is possible, he added, that the virus attack has left damaged nerves in its wake.

Other chronic pains can be so recalcitrant that Eltherington refers the patients to other specialists, such as Dr. Ken Peters of the Northern California Headache Clinic in Mountain View, and Dr. Arnold Kresch, a gynecologist and psychiatrist in Palo Alto. Both are members of the clinical voluntary faculty at Stanford.

Anesthesiologists with Stanford's pain service, including Eltherington, Dr. William Forrest, and Dr. John Bunker, try to silence pain impulses with nerve blocks.

They can destroy a nerve with an injection of alcohol or phenol. Or, a probe can be used to heat or freeze a pain-producing nerve into submission.

Eltherington said he always use a reversible test before killing a nerve— first he numbs it with an anesthetic to see if the pain subsides.

He also uses this anesthetic test to sort out complicated pain puzzles such as stress versus migraine headaches, or to find the source of abdominal and pelvic pain.

Even permanent nerve blocks often provide only temporary respite, but with some problems such as testicular neuralgia (usually caused by a straddle injury) and reflex sympathetic dystrophy, the technique can give a complete cure.

Similarly, some chronic pains are relieved by injecting steroids into an inflamed nerve to ease its swelling.

Other drugs are given by mouth in an attempt to interrupt a reverberating message that chronic pain can set up inside the brain.

Like a bad memory, the signals can echo on, even after the original source of pain is removed, Eltherington said.

This "central pain" can tell a paraplegic "your knee hurts," although the patient's broken spinal cord makes it impossible for the brain to receive any actual sensation from the legs, he said.

So he tries anti-epileptic drugs on spinal injury patients in pain, and a tranquilizer plus an anti-depressant for people with post-herpetic neuralgia.

If these methods fail, patients can go to physical therapy for a trial with a transcutaneous nerve stimulator (TNS).

Just as it helps to rub your elbow after you bang it, the TNS can cover up pain by activating other nerve fibers besides the ones that carry painful signals, said Smithline, who is clinical coordinator of physical therapy outpatient services for Stanford University Hospital.

Flat electrodes taped to the skin and powered by a palm-sized battery pack mask pain by electronically stimulating a painful area. The current may also cause nerve cells to release endorphins and enkephalins, which are the body's own painkiller molecules, she said.

more

Occasionally she has seen dramatic results with the TNS, but more often, its success is short-lived.

So Smithline uses insights from her initial evaluation of patients to work on their pain with simpler techniques.

Heat and ice packs can ease aches and prime the body for exercises to increase joint movement and stretch painfully tight skin and muscles, she said.

Such therapy can loosen the stiff neck of a post-herpetic neuralgia patient who has held his whole torso rigid because of the pain, she said. And a limb long immobilized by reflex sympathetic dystrophy can be recruited back to use by manipulating the joints and limbering the muscles.

When pain sits deep, heat generated by an ultrasound device can penetrate to soothe and loosen tight tissues.

Most important, Smithline teaches patients to treat themselves. A man with chest pain taught to massage the skin surrounding his scar eased his discomfort and freed his movements, she said. Massage also aided a woman whose migraines were compounded by tension headaches, especially since her boyfriend learned the technique, Smithline said.

"We try to incorporate the family (into the therapy)," she said.

More self-help is available for back pain at the Stanford Back School, where four one-hour sessions show the proper way to sit, stand, clean house, garden, lift, and rest, Smithline said.

And while a patient can learn better posture and acitivity habits through physical therapy, clinical staff psychologists Drs. Mark Pratt, Andy Carman, and Hugh Baras assist with managing stress.

Biofeedback monitors can reveal the tense muscles, sweaty palms, and restricted blood flow to the hands that signal over-reaction to stress, said Pratt. Presence of these tension signs suggests that biofeedback training could help a person manage his or her pain, he said.

Through biofeedback, a patient can learn to spot which muscles are knotting with tension, and how to relax them. And many migraine sufferers can learn to derail an oncoming headache by redirecting the flow of blood from their heads to their hands, said Pratt.

Depression often accompanies chronic pain, not surprisingly, but it can interfere with a patient's response to treatment, Pratt said. He recommends anti-depressant medication combined with psychotherapy for pain patients who are depressed.

He also sees if personality factors are adding to a person's stress level. For example, if a worker always assumes he is the target of anger each time his boss slams the door, he may be aggrevating his pain by over-reacting to other people. Analyzing a person's "cognitive processes," —what you say to yourself—might give hints to reduce tension and thereby pain, Pratt said.

Indeed, important obstacles to overcoming pain may lie within the patient's own mind, he said.

Eltherington added that most chonic sufferers have developed "pain behavior," and have allowed their physical distress to govern all aspects of their lives.

Therapy to modify behavior is "one of the best treatments" for patients with ingrained habits built around years of pain, he said.

People can deal positively with having to live with pain by using distraction, Pratt said.

"Don't abandon previous sources of pleasure," Pratt advised. "If you can't jog, then swim."

Mild exercises—walking, swimming, wading chest-deep in a heated pool—are the clinic's favorite prescription for turning the diability of chronic pain into merely a handicap.

Fear of adding to their pain has kept his patients inactive, Eltherington said. But, he said, "for the vast majority," those fears are unfounded.

"You can either sit home doing little or nothing, or be swimming laps," he said, and your pain will be "absolutely the same."

MENOPAUSE MISUNDERSTOOD

STANFORD—
Menopause no longer need be a traumatic event in a woman's life. Treatments for its symptoms are continually improving, and some of its effects can be prevented.

Once considered the scourge of old age for women, menopause no longer need be a source of apprehension. Its worst effect, osteoporosis, can be prevented and treated. Its symptoms — such as hot flashes, mood swings and depression — can be treated as well. Signaling the end of fertility, menopause can have a liberating effect for women. The more medicine learns, the more it's apparent that some of the changes menopause brings can, in fact, be for the better.

Stanford physicians are adding to medicine's knowledge about menopause. Endocrinologist Dr. Robert Marcus, aging study unit director at the Geriatrics Research Education Clinical Center at the Palo Alto Veterans Administration Medical Center, recently initiated a research, education and treatment program for osteoporosis, a bone disease affecting about 20 million post-menopausal women. Physiologist Dr. Julian Davidson is studying the effects of hormonal changes that occur during menopause on sexual functioning. Together with physicians all over the world, they are working to learn about all the causes and consequences of menopause and to sort through the controversies of treatment and prevention. By doing so, they hope to provide women with the most effective and unimposing way in which to deal with this midlife rite of passage.

"Menopause has traditionally been considered a disease of sorts, but it's not," Davidson says. "It is a natural change of life with some very beneficial aspects."

Menopause, the cessation of menstruation, typically occurs in women in their late 40s and early 50s. It begins with a decrease in the levels of two key players: the hormones estrogen and progesterone.

"Estrogen causes all human changes that we consider feminine," says Dr. Emmet Lamb, gynecology-obstetrics professor, "such as body contours, fat distribution, breast development and other pubertal changes. Progesterone," he continues, "causes the changes in the lining of the uterus necessary for a fertilized egg to burrow itself and start to develop. It causes the secretion of a nutrient-filled fluid that supports the egg as well."

In a normal menstrual cycle, ovarian cells band together to form sacs, called follicles, which hold the eggs. As part of their activity, the follicles produce estrogen and progesterone. The estrogen travels through the bloodstream to numerous places, including an area in the base of the brain called the hypothalamus, which is responsible for the control of basic body functions such as temperature. The hypothalamus registers how much estrogen is present and responds by secreting a chemical called GNRH, gonadotropin releasing hormone. The GNRH travels to the pituitary gland, located near the hypothalamus and responsible for secreting some hormones. The pituitary gland reacts by releasing FSH, follicle stimulating hormone, and LH, luteinizing hormone. While the LH is responsible for ovulation, the FSH stimulates the follicles to produce more estrogen.

..ore

Women are born with a finite number of eggs — about 400,000 — to use during their lifetime. Yet only a fraction of these — one a month during women's fertile years — are actually released from the follicles with fertilization potential. By the time menopause sets in, Lamb explains, women have essentially run out of eggs. Without the eggs, the follicles fail to produce enough estrogen to keep the cycle going, basically shutting down the reproductive system. And the lack of enough progesterone fails to trigger the uterus lining to slough off cyclically in the form of menstrual bleeding. When the hypothalamus, which also sends out electrical impulses to other parts of the brain, does not receive enough estrogen to control its function, it goes a bit berserk, Lamb says. The result? Menopause's well-known side effects, the most common of which are hot flashes.

Hot flashes are not, as was once the popular thought, just an illusion. Work by Dr. Howard Judd at University of California, Los Angeles, has shown an actual physiological event that causes the hot feeling, the flush and the sweating. "The estrogen-deprived hypothalamus sends out a wrong signal telling the body to react as if it were in a hot room," Lamb says.

Each hot flash lasts a few minutes. Their rate of occurence differs drastically from individual to individual. Further work by Judd showed that they interrupt women's REM sleep. "When anybody is deprived of sleep, they get crabby. This is what accounts in large part for the mood swings and depression," Lamb says.

In collaboration with San Francisco State University psychologist Dr. Norma McCoy, Davidson has found that women who maintain a consistent sex life are less apt to experience hot flashes. Published in the October, 1985 issue of *Archives of Sexual Behavior*, a study of 43 women, which the authors say is the first of its kind, established that a "close association exists between increasing irregularity of menstrual cycles, hot flashes, declining estrogen levels and declining frequency of intercourse." What are the possible explanations for the association?

"First, the discomfort of hot flashes and other associated menopausal symptoms might have an inhibiting effect on sexual behavior," the authors surmise. "Second, regular sexual activity might have a protective action against lowering hormone levels and therefore its absence is associated with the disruption of cycles. Finally," McCoy and Davidson write, "the association between hot flashes and reduced frequency of sexual intercourse may be the result of some common third variable."

A possible solution, then, may be for aging women to maintain an active sex life, though Davidson points out this has yet to be proven. While the absence of ovulation may alleviate women's fears of pregnancy, he says, other factors may negate that sense of liberation. In other studies comparing pre- and post-menopausal women, he found that those who had gone through menopause experienced a decline in sexual thoughts and fantasies. He and his colleagues were also able to physiologically measure a decline of vaginal lubrication and frequency and satisfaction of intercourse.

These symptoms, however, do not have to seriously affect sexual functioning, Davidson continues. Together with hot flashes and other menopausal side effects, they may be treated with what physicians now universally recognize as the most effective treatment: estrogen replacement therapy (ERT).

ERT has been a source of controversy over the years; the most recent rift surfaced when it was associated with cancer of the uterus lining, the endometrium. The cancer occurred, Lamb explains, because there was nothing to trigger the unused lining to slough off. That risk has been eliminated, however, by adding a progesterone-like agent towards the end of the cycle. Women may have some menstrual-like bleeding, he adds, but it is only to rid their bodies of unused and unwanted cells.

"There's lots of justifiable confusion on the part of the public concerning ERT because medicine has gone back and forth so often," Marcus says. "But there is no question of its efficacy."

ERT has been associated with other potential problems as well, such as gallbladder disease, hypertension and blood clots, but these risks are far outweighed by its benefits in treating hot flashes, vaginal atrophy, depression and in preventing heart disease and osteoporosis.

Osteoporosis —"porous bones"— afflicts about 20 million post-menopausal women. The skeleton's most common disease, it is triggered by a lack of calcium due to the lost ability estrogen provides for bones to hold onto minerals. The spine, vertebrae, pelvis and other bones become thin and brittle, Marcus says.

As a result, a mere slip on a rug, or lifting a bag of groceries, can fracture an older woman's wrist or hip. The stoop many older woman develop, known as dowager's hump, is caused by weakened vertebrae that collapse under body weight. More than one million fractures each year occur in osteoporosis victims, at a cost of nearly $4 billion. About 15 percent of women with hip fractures die within three months, Marcus notes, because of complications such as pneumonia, blood clots and stroke, due to immobilization.

But, Marcus points out, osteoporosis can be prevented and treated. And the sooner women start doing so, the better.

"We recognize that it's good to deal early with osteoporosis," he says. At adolescence, when the body is laying down its final amount of bone, Marcus explains, proper diet and exercise are key to building dense bones that will withstand the effects of osteoporosis later on.

A living tissue, bone requires constant renewal and repair throughout life. In the cyclic process called bone remodeling, bone-stripping cells, osteoclasts, resorb calcium from bone while bone-forming cells, osteoblasts, replace it to form new tissue. During adolescence, Marcus explains, bone density reaches its peak because tissue formation outpaces tissue removal.

Bone loss begins for most women around age 35 when the scales tip in the opposite direction. The loss begins slowly — less than one percent per year — but increases significantly during menopause, Marcus says. Thin, white women are most susceptible; black women are among the least affected. A family history of the disorder, heavy alcohol and caffeine use, smoking, high-protein diet and lack of exercise are believed to contribute to osteoporosis.

"As women enter the age of menopause we should determine the risk of osteoporotic fractures by measuring bone mass. Sequential measurement gives an estimate of the rate at which the bone is being lost. Then we can advise the best regimen."

At Marcus' clinic, women can undergo bone analysis by either a specialized X-ray procedure called computerized tomography (CT scan), or a new and not yet widely available procedure called dual-photon absorptionometry (DPA), which measures the amount of mineral present in bone. "We are one of the few facilities in the area offering DPA," Marcus notes.

Once bone loss begins, he continues, ERT is almost always prescribed, though the dosage can be tailored to each individual's needs. In addition to its other menopausal benefits, estrogen helps maintain bone mass.

"It's unlikely that we'll ever swing back to rejecting estrogen," Marcus says, though through research medicine may find ways of using it more selectively. But until then, it helps women get through what was once a traumatic event in their lives.

"Menopause doesn't have to have a great effect on women," Davidson says. "It still seems to dominate some women's lives. Yet others," he adds, "hardly even notice."

Preventing osteoporosis

Arming your body against osteoporosis should be a lifelong process, physicians say. Adopting healthy habits in your teens or early adulthood may help you avoid menopausal complications in later years. Here are some tips that may not only prevent osteoporosis but may give you a healthier lifestyle overall.

- Eat a calcium-rich diet. Children aren't the only ones who need calcium for growing bones. If your diet does not contain enough calcium, your body will cannibalize your bones in order to maintain calcium levels in your blood. "Women as a group grossly underconsume calcium, especially teens who often substitute colas for milk," endocrinologist Dr. Robert Marcus says. Women need the equivalent of a quart of milk per day until age 50, he adds, and a quart and a half of milk after that. For those who can't consume dairy products, Marcus says, calcium supplements of up to 1,500 mgs. a day are recommended.
- Calcium can be consumed in the form of milk and other dairy products such as cheese, yogurt and ice cream. Chicken bones also contain a lot of calcium, as do small fish and dark, leafy vegetables.
